Johnson

OFFICERS OF THE SECTIONS FOR 1941

ELECTED BY THE SECTIONS

The street addresses may be obtained from the *Directory of Officers and Fellows*

SECTION OF MEDICINE

Chairman A A Hornor Boston *secretary* C L Short Boston

SECTION OF SURGERY

Chairman N R Hatt Springfield *secretary* S J G Nowak, Boston

SECTION OF PEDIATRICS

Chairman H L Higgins Boston *secretary* J M Baty Belmont and Brook
line.

SECTION OF OBSTETRICS AND GYNECOLOGY

Chairman M F Eades Newtonville and Boston *vice chairman* C J Duncan,
Brookline *secretary* R S Titus, Boston

SECTION OF RADIOLOGY AND PHYSIOTHERAPY

Chairman C L Payzant Boston *secretary* J H Marks Boston

SECTION OF DERMATOLOGY AND SYPHILIGOLOGY

Chairman W P Boardman Boston *secretary* Jacob H Swartz Boston

OFFICERS OF THE DISTRICT MEDICAL SOCIETIES

ELECTED BY THE DISTRICT MEDICAL SOCIETIES AT THEIR ANNUAL MEETINGS BETWEEN APRIL 15 AND MAY 15 1940

The street addresses may be obtained from the *Directory of Officers and Fellows*

BARNSTABLE — *President* O S Simpson Falmouth *vice president* J G Kelley
Pocasset *secretary* D E. Higgins Cotuit *treasurer* H F Rowley Harwich Port
librarian E E. Hawes Hyannis.

BERKSHIRE — *President* J W Bunce North Adams *vice president* W A Millet
Pittsfield *secretary* G S Reynolds Pittsfield *treasurer* C T Leslie Pittsfield

BRISTOL NORTH — *President* R M Chambers Taunton *vice president* J A
Leese Attleboro' *secretary* W H Swift Taunton *treasurer* J V Chatigny
Taunton

BRISTOL SOUTH — *President* H E Perry New Bedford *vice president* H P
Sawyer Fall River *secretary and treasurer* A H Sierns New Bedford

ESSEX NORTH — *President* R C. Norris Methuen *vice president* C W Bullard
Newburyport *secretary* H R. Kurtz Lawrence *treasurer* G L. Richardson
Haverhill

ESSEX SOUTH — *President* Loring Grimes Swampscott *vice president* F R.
Ireson Marblehead *secretary* J R. Shaughnessy Salem *treasurer* Andrew Nichols
Ili Danvers

FRANKLIN — *President* A H Wright Northfield *vice president* A W Hayes
Greenfield *secretary and treasurer* H L Craft Ashfield

HAMPDEN — *President* J B Bigelow Holyoke *vice president* G B Corcoran
West Springfield *secretary and treasurer* W C. Barnes Springfield

HAMPSHIRE — *President* J M Murphy Florence *vice-president* Mary P Snook
Chesterfield *secretary and treasurer* J D Collins Northampton *librarian* Abbie M
O Keefe, Northampton

MIDDLESEX EAST — *President* G R. Murphy Melrose *vice president* J M
Wilcox Woburn *secretary* A L. MacLachlan Melrose *treasurer* Richard Dutton
Wakefield *librarian* J M Wilcox Woburn

MIDDLESEX NORTH — *President* W M Collins Lowell *vice president* W H
Sherman Lowell *secretary* R L Drapeau Lowell *treasurer* M D Bryant Lowell
librarian P J Meehan Tewksbury

MIDDLESEX SOUTH — *President* Dwight O'Hara Waltham *vice president* H F
Day Cambridge *secretary* A A Levi Newton *treasurer* Edward Mellus Newton
orator H G Giddings Newton

NORFOLK — *President* F P McCarthy Milton *vice president* S A Robins
Roxbury *secretary* F S Cruickshank Brookline *treasurer* Frederick Reis Jamaica
Plain

NORFOLK SOUTH — *President* D B Reardon Quincy *vice president* W L
Sargent Quincy *secretary and librarian* H H A Blyth Quincy *treasurer* F W
Crawford Holbrook

PLYMOUTH — *President* S W Goddard Brockton *vice president* G A Moore
Brockton *secretary* R C McLeod Brockton *treasurer* A M Champ Brockton
librarian J H Weller State Farm

SUFFOLK — *President* A A Hornor Boston *vice president* J P O'Hare Boston
secretary M H Clifford Boston *treasurer* W T S Thorndike Boston

WORCESTER — *President* J M Melick Worcester *vice president* R. S Perkins
Worcester *secretary* G C Tully Worcester *treasurer* E P Disbrow Worcester
librarian emeritus A C Getchell Worcester

WORCESTER NORTH — *President* B P Sweeney Leominster *vice president* H C
Arey Gardner *secretary* E. A Adams Fitchburg *treasurer* F H Thompson Jr,
Fitchburg

NUMBER 1

THE TURN OF THE CENTURY — AND AFTER*

DAVID CHEEVER, MD†

BOSTON

MY talk this evening to which I have given the above title, I will describe as a fairy tale, dealing like most fairy tales, with events of long ago, for such it seems to me. Imagine me as a prospective student presenting myself in late September of 1897 at the door of the Harvard Medical School on the corner of Boylston and Exeter streets, Boston—a building constructed for the school fourteen years earlier and representing the acme of convenience and suitability and believed to be adequate for at least three generations, yet already having quarters cramped for laboratory studies on account of the vast progress being made in the medical sciences. An impressive white bearded man of responsible appearance greeted me. This was James Skillen, always known as Jim, a former male nurse or operating room orderly at the Massachusetts General Hospital and promoted to be janitor of the medical school when it moved from the old building on North Grove Street to its new quarters. Jim lived in the school, and with his wife, Susie, and daughter, Nellie, ran it most effectively—ably assisted, of course, by the dean and faculty of the school. He knew every student and faculty member and spoke of the latter with entire respect but considerable familiarity, by their first names. Perhaps in contrast a picture should be presented of the great educator under whose direction the medical course was conducted, President Charles W. Eliot. It is impossible to do more than touch upon his influence. Mr. Eliot assumed the presidency of Harvard University in 1869, and immediately evidenced his interest in the medical school and his sense of the unity of the school with other graduate departments to form the university, by attending and presiding at the faculty meetings. It was essentially a proprietary school, with a curriculum of four months of lectures during each of two years. In addition to attendance at exactly

the same lectures in succeeding years, the students were required to spend their additional eight months of each year and one succeeding year in an apprenticeship to some acceptable practitioner, or indeed in one of the very few available house officer posts at the Massachusetts General Hospital or in the recently established Boston City Hospital. It was only necessary for the student to pass perfunctory examinations in five of the nine lecture courses in order to obtain his degree. The school had little or no endowment, and the nine professors and a few assistants were paid from the proceeds of the tickets which were sold for their lectures. Mr. Eliot increased the course to three years of graded instruction, introduced adequate written examinations, advised greater contact of students with patients, in the form especially of section teaching and explained to Professor Henry J. Bigelow, who in faculty meeting with groans deprecated the numerous changes, that the reason they were occurring was because there was a new president. Later came the addition of the fourth year to the curriculum and the requirement of an A.B. degree or its equivalent for admission. Mr. Eliot showed a similar interest in elevating dental education to its appropriate place as a department of general medicine. He urged the systematic teaching of preventive medicine, defended free experimentation and vivisection and promoted the recognition of medical service as a part of the social organization. His contributions to medical education were incalculable.

The first teacher with whom I came in contact was Thomas Dwight, Parkman Professor of Anatomy, one of the men about whom one could say, as did a contemporaneous biographer of a colleague, "He was a legendary Bostonian with all the crushing disadvantages of an assured position, binding tradition and a competence." Dwight graduated in medicine in 1867, and the picture of him showing a dignified, grave teacher with a full beard scarcely suggests the slender active young man who, tradition says, while operations were

*Read before a meeting of the Harvard Medical Society at the Peter Bent Brigham Hospital, Boston, May 16, 1939.

†Associate professor of surgery emeritus, Harvard Medical School; senior consultant, Peter Bent Brigham Hospital, Boston.

conducted in the amphitheater at the Massachusetts General Hospital under the carbolic vapor of Lister sprayed over the field from a foot-driven machine, was entrusted with a hand atomizer to promote additional efficacy, and as he bobbed up between the members of the operating group to deliver a spray over an area where it appeared to be especially needed, received many a sharp rap

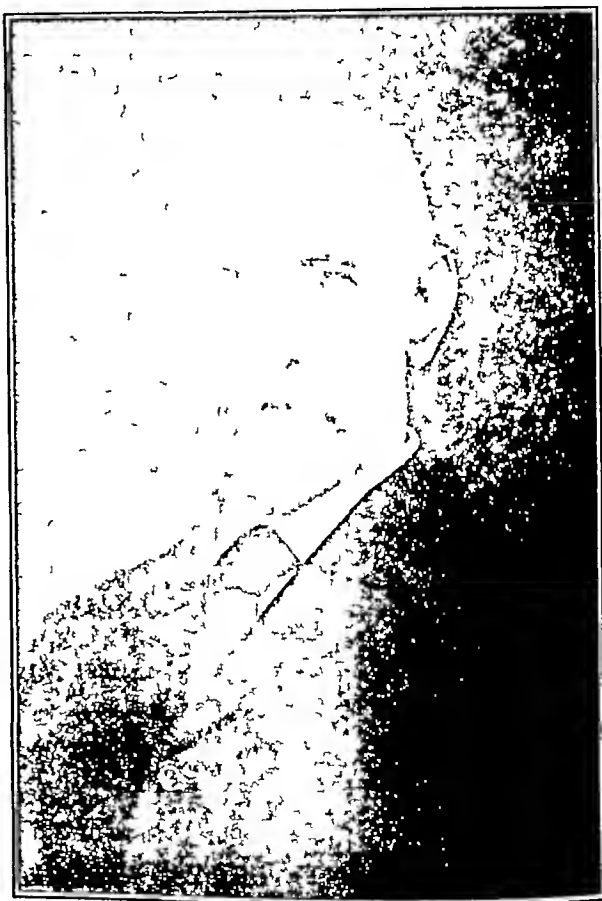

THOMAS DWIGHT

on the cranium or knuckles with the instrument in the hand of the attending surgeon. Dwight studied abroad with Rudinger at Munich, and on his return began to practice medicine and surgery, but his heart was in anatomy; he taught comparative anatomy, histology and embryology and was finally entrusted with the professorship on the retirement of Oliver Wendell Holmes. He was an effective and enthusiastic teacher, he took his duties seriously, and being a man of great faith and spirituality impressed upon his students a sense of the privilege which was accorded to them in dissecting the tenement of clay from which the soul had fled, and obtained from them the respect and decorum appropriate to the occasion. Dwight was a morphologist, and made important researches in the normal variations of the skeleton, and with Mr. Emerton, the artist and technician, he made the superb large scale models of the bones of the skeleton which, with other means devised by him, contributed to the supreme excellence of the instruction in anatomy.

The subject of anatomy should not be closed without speaking of the demonstrator and the assistant demonstrators, a group of young surgeons, enthusiastic and interested in their work because they knew that skill in gross anatomy and dissection was the open sesame to success as surgeons, which perhaps without exception they attained. Nor should mention be omitted of Tom Bonney, the devoted and intelligent preparateur of the anatomical material, whose term of service, begun in 1892, is just now, as this is written, coming to a close.

Simultaneously with Dwight I met another great personality, Charles Sedgewick Minot, professor of embryology. Minot had the same sort of personal background as did Dwight, indeed it was actually he who was described as the "legendary Bostonian" above-mentioned. Minot was a born

CHARLES SEDGEWICK MINOT

naturalist, he studied insects and flowers while still a schoolboy, obtained his degree in science at the Massachusetts Institute of Technology, studied with Ludwig in Leipzig and came home well trained in the biological sciences and in chemistry. No doubt he might have excelled in the latter, but he preferred morphology and mastered the technique of microscopy, he first taught embryology in 1880.

and finally took charge of the Department of Histology and Embryology in 1892, with further promotion to become James Sullman Professor of Comparative Anatomy in 1905. As the scientific world knows, he made an almost unrivaled collection of the embryos of various vertebrates and perfected the microtome, superintended the staining of sections of one hundred and fifty complete series of pig embryos for study by the students, and wrote a standard treatise on embryology. I remember him as a moderately tall, very erect, well-knit figure standing behind the laboratory desk upon which rested his fingertips, describing with great deliberation, and with faultless, clean-cut enunciation, the intricacies of his subject, illustrating it also frequently with graphic diagrammatic drawings on the blackboard, of textbook perfection. He introduced us to a Dutch motto sent to him by Professor Hubrecht of Utrecht, which was displayed in large letters and framed on the wall: *Wat baaten kaers of bril als den uil niet sien uit?* which he translated as follows: "Of what use can light and lenses be if owlets look and will not see?" Minor believed in meticulously ascertaining and recording the student's daily work, he constructed a board looking somewhat like a cribbage board, the holes in which represented the desks of the individual students, and pegs of different colors to represent the instructors, whose personal supervision over the students was thus followed.

The course in physiology introduced me to another teacher of equal notability, Henry Pickering Bowditch, professor of physiology. As one looks at the sedate figure in cap and gown one can scarcely picture him as a brilliant cavalry officer who served throughout the Civil War in the First Massachusetts Cavalry, and who entered Richmond as a major in 1865. Bowditch was a grandson of Nathaniel Bowditch, the mathematician and navigator, and son of a successful Boston merchant, so that he also seems to be one of the legendary Bostonians who made a mark for himself in spite of handicaps of birth. Returning from the war, he graduated in medicine at Harvard in 1868, and then studied in Paris with Claude Bernard and in Leipzig with Carl Ludwig, on returning to Boston he established the first physiological laboratory for students in the United States and engaged in researches in general biology, experimental pharmacology, pathology, psychology and surgery. I remember his emphasis on productive scholarship, his inventiveness, his clear lectures and supplementary recitation periods. He introduced the plan of sending students to the original sources for material for physiological theses. He gave the impression of high breeding and was conspicuous for courtesy, fairness and good

will, and sometimes failed to suppress in a classroom his sense of humor. During his long career as a teacher of physiology he actually established laboratories in three separate buildings: North Grove Street, Boylston Street, and finally in the present buildings on Longwood Avenue. Together with J. Collins Warren, he was more in

HENRY PICKERING BOWDITCH

JOHN COLLINS WARREN

instrumental than any other in planning the expansion of the medical school and enlisting the interest of public spirited men in the project. He was deao of the school from 1883 to 1893. He sought out and brought to Harvard promising men from other universities; he was a public spirited citizen, always to be depended on to help defeat the unwise and to promote the wise in state legislation. The picture displayed of him garbed in cap and gown and seated with Warren at the time of the dedication of the new buildings in 1906 does not do justice to his expressive and interesting face, because it perhaps betrays the existence of the chronic illness which was already spreading its mask over his features.

Chemistry was taught by Edward Stickney Wood, who, having graduated from Harvard College in 1867 and from Harvard Medical School in 1871 and completed a surgical internship at the Massachusetts General Hospital, studied in Berlin and Vienna and began teaching as adjunct

professor to James C White, who was later to enter the field of dermatology Wood became full professor in 1876, though not a genius, he was a remarkable teacher who gave the impression of perfect mastery of his subject Interest was added to his personality by the fact that he was the most famous medical expert witness of his day and was often quoted on the front pages of the daily papers in connection with some murder trial or other medicolegal problem of absorbing interest His students could well believe that as a medical expert witness he was without an equal—cool, calm, impartial and imperturbable under cross-examination It is said that his advice was much relied upon by Mr Eliot

In pathology I was fortunate in having a teacher unusual both in ability and in personality, William Thomas Councilman, who, descended on his father's side from a settler from Holland and on his mother's side from Scotch-English forebears, was the son of a country physician and farmer in Maryland He was a born naturalist, and while working on the farm as a boy made a collection of bones illustrating the comparative osteology of the indigenous vertebrates After studying medicine at the University of Maryland he passed two years abroad with Chiari in Vienna, Cohnheim and Weigert in Leipzig and von Recklinghausen in Strasbourg, and on returning in 1892 joined Welch in teaching pathology at the recently founded Johns Hopkins Medical School He was called to Harvard as the third Shattuck Professor of Pathological Anatomy, succeeding Reginald H Fitz, and became pathologist to the Boston City Hospital, whither he attracted among others Dr Frank B Mallory, weaning him from clinical practice to pathology Councilman was a man of great activity and enthusiasm in teaching and research He promoted the appointment of a full-time pathologist at the Massachusetts General Hospital in 1896, in 1913 he became pathologist to the Peter Bent Brigham Hospital, which had just opened its doors His was a colorful personality, as a biographer states, he "cultivated neither reserve nor mannerisms but achieved dignity by virtue of directness, competence and honesty" He inspired his students with the ambition to become independent observers and thinkers He often acted on impulse regardless of the conventions On one occasion at the Boston City Hospital, having just completed an autopsy he received a telephone message from the superintendent which irritated him, instantly, without coat and vest or collar and necktie, with red suspenders and underwear conspicuous, he rushed across the yard and through the buildings and passageways to "Center" where he had a talk with the astonished and

probably quite reasonable McCollum The photograph of him shows him seated looking reflectively at his dog, Pasco, lying on his desk Pasco was the offspring of a Boston terrier belonging to Louis Pasco, familiar to more than one generation of medical students as the keeper of the morgue at the Boston City Hospital In his last years, after his retirement, Councilman suffered from, but was not cowed by, attacks of angina pectoris, for the relief of which he always carried a bottle of nitroglycerin

Harold Clarence Ernst, professor of bacteriology, was a pioneer in that branch On the paternal side he was descended from a German grandfather who migrated from Prussia during the Napoleonic Wars and married a Boston lady of old New England stock It is not frivolous to record that Ernst, who graduated from Harvard College in 1876, was one of the best amateur base-

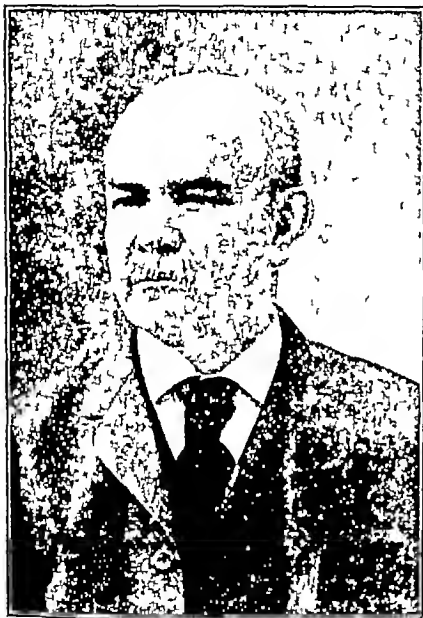

WILLIAM THOMAS COUNCILMAN

ball pitchers of all time, he is said to have added one more to the different types of curves which could be imparted to a thrown ball, and received flattering offers to become a professional After receiving his medical degree in 1880 he studied with Koch in Berlin, and on returning to this country gave six lectures on bacteriology in 1885 at the Harvard Medical School, probably the first lectures on that subject given in a medical school in the United States It was hard work against opposition to establish the importance of bacteriology Ernst developed the first sterilizing apparatus at the Massachusetts General Hospital, and for years supplied from his own little laboratory all the vaccine and antitoxin used by the City of Boston, and also tuberculin for the inoculation of cattle He became first professor of bacteriology in 1895 and held the office until 1922 His students remember him as a tall man, large of frame, of austere and rather stern military appearance, which was much confirmed by his uniform in the World War, which gave him the appearance of a

Prussian military officer. He was an able man of strong character and great courage and devotion to high ideals, which led him to many types of public service and to the laborious editorship of the *Journal of Medical Research*. It was fortunate that the infant subject of bacteriology should have found such a forceful and competent champion.

The theory and practice of physic was taught by the Hersey Professor, Reginald Heber Fitz, who graduated from Harvard College in 1864 and from Harvard Medical School in 1868, and who was then surgical house officer at the Boston City

REGINALD HEBER FITZ

Hospital. Two years were then spent in Europe with Rokitsansky, Oppolzer and Skoda in Vienna and Cornil in Paris, whence he returned to be one of the first to introduce into America Virchow's ideas in regard to cellular pathology. He approached clinical work through the pathological laboratory and autopsy room succeeding John B. S. Jackson as professor of pathological anatomy, becoming visiting physician to the Massachusetts General Hospital in 1887 and finally reaching the obvious objective of Hersey Professor of the Theory and Practice of Physic in 1892. His teaching began just at the establishment of the three full years of instruction with written examinations and the

requirement that every student must pass every course, and just at the beginning of laboratory teaching in physiology and chemistry. He exercised a profound influence on medical education, being chairman of the Committee on Curriculum for many years. He persuaded Henry F. Sears to give the first laboratory in America devoted exclusively to the study and teaching of pathology, housed in an addition to the building on Boylston Street. All the world knows his most conspicuous achievement the demonstration of the responsibility of the appendix for the majority of inflammatory conditions in the right iliac fossa, brought to the attention of the world in a paper entitled "Perforating Inflammation of the Vermiform Appendix," read in 1886 before the Association of American Physicians. This paper gave the first clear picture of the pathology and clinical aspects of the disease and advocated operative interference. Three years later he urged the then startling innovation of the interval operation, and the same year published a paper on acute pancreatitis, which described fat necrosis. These are merely the most striking of his many important contributions. Fitz met the students in a series of systematic lectures and in amphitheater clinics and recitations. The lectures were remarkable as models of clear and precise exposition rapidly delivered at a rate which made it almost impossible to take complete notes. In the clinic he required a student before the class to secure the main features of the history of a patient, make a physical examination, perform or ask information about necessary laboratory tests and then make and defend a diagnosis and suggest treatment. The ability and learning of the man and the precision which he required in observation, interpretation and exposition were not soon forgotten. He permitted the student to fall headlong into the inevitable pitfalls, whence he rescued him with humorous irony which disconcerted the victim but delighted his fellows—a method of pedagogy which Fitz well knew was second to no other in making a lesson unforgettable. He delighted in argument and discussion and waxed more cheerful in opposition, though he was tenacious of nothing but the truth. I always felt admiration and respect, not unmingled with fear until later when I came into more personal relations with him and was able to confirm my suspicions of friendly kindness. A biographer says, "There must be many who owed him their best ideals in medicine."

John Collins Warren, the fourth in the Warren surgical hierarchy, great grandson of the founder of the Harvard Medical School and grandson of one of the founders of the Massachusetts Gen-

eral Hospital, was head of the Department of Surgery After graduation from Harvard University in arts and in medicine, he visited Lister in Glasgow, studied the antiseptic method at the hands of its creator and brought it back to America He was particularly interested in surgical pathology and wrote an admirable textbook on that subject, and as a matter of course, he joined the surgical staff of the Massachusetts General Hospital and the faculty of the Harvard Medical School, and in 1899 was made Moseley Professor of Sur-

FREDERICK CHEEVER SHATTUCK

gery Neither as a surgeon nor as a teacher was he endowed with great genius, but in the former capacity he was courageous, resourceful and thorough, and in the latter he gave much time to the preparation and conduct of his teaching With the traditions of three distinguished generations pointing out his own duty and destiny, his life was a fulfillment of the adage, *Noblesse oblige*, and throughout he was a beacon light of personal distinction, charm and public usefulness With Bowditch he conceived the magnificent project for the new school, and with his happy faculty of securing and sustaining the interest of others he had much to do with securing the necessary support, he was one of the first to advocate the plan for a dormitory He was chairman of the Cancer Commission of Harvard University and secured the

funds for the Collis P Huntington Memorial Hospital The respect and affection in which he was held increased with his years and were in direct proportion to a contemporary's capacity to perceive the elements of true character The continuity of the Warren tradition is a most enviable heritage for the Harvard Medical School and for the medical profession of Boston

The next portrait is that of the professor of clinical medicine, Frederick Cheever Shattuck, obviously another legendary Bostonian with the accompanying handicaps He was the fourth in line of able physicians Perhaps through his many-sided personality, his extraordinary charm and his wisdom he made as deep an impression on succeeding classes of medical students and house officers as did any other of their teachers He had studied in London, Paris and Vienna, and brought home high standards of careful history-taking and of physical examination Something — perhaps it was his very youthful appearance — militated against his immediate success in building up a practice, but he utilized his time to advantage with patients and students in the Out Patient Department of the Massachusetts General Hospital The exercises he conducted were always clinical in character, and it was his actual relation with patients, his sympathetic understanding of their woes, his humorous but never satirical touch, which would best exemplify to the students the methods of the wise physician He was astute in diagnosis and daring in his treatment It was wisely stated that he was a successful psychotherapist long before that term was coined The statement that is said to have been current in some laboratories that medicine can be practiced without seeing the patient was scornfully repudiated by him He was fond of saying that the final test of all diagnostic and therapeutic measures is made at the bedside rather than in the laboratory His fundamental success as a teacher gave authority to his opinion that a full-time teacher, trained only in the laboratory and hospital ward, can impart only a partial knowledge of the practice of medicine His was a picturesque figure as he drove about the city in an open victoria, with a cigarette between his lips, a carnation in his buttonhole, a gaudy waistcoat and with reading matter — medical journals or letters — piled up on the seat beside him, and attended by Hans, the dachshund No better influence did the medical students encounter among their preceptors than that of Shattuck He lived through a period of enormous development in the medical sciences and their application In these matters he was not so much a pioneer as an interpreter and practitioner

Another portrait is presented, that of David Wil-

liams Cheever, because though officially retired from the active teaching staff he was called on by the students to give lectures on special subjects. He graduated from Harvard College in 1852 and from Harvard Medical School in 1858, where he worked hard in the only laboratory course then given, that of anatomy. His proficiency attracted

DAVID WILLIAMS CHEEVER

the attention of Oliver Wendell Holmes, who appointed him to prepare his dissections and made him demonstrator of anatomy—a position which in those days was the most universally accepted steppingstone to surgery. Thus he was ripe for the opportunity offered with the opening of the Boston City Hospital in 1864, and was the first surgeon appointed to its staff and performed the first surgical operation. Medical students were attracted to the new institution, and it is a tribute to his success as a teacher that the professorship of surgery should have passed to him from its legendary home, the Massachusetts General Hospital, on the retirement of Henry J. Bigelow. Cheever's teaching was largely clinical at the hospital but he exemplified the fact that the now somewhat disparaged didactic lecture may be, in good hands, an excellent vehicle of instruction. He was a remarkable lecturer who spoke extemporaneously but after the most careful preparation and

digestion of the subject beforehand. He used no oratorical or elocutionary arts. He did not draw on the blackboard and cultivated no mannerisms to awaken attention. He gave a condensed, lucid, simple, epigrammatic word picture of his subject, so terse and convincing that his hearers could not afford to miss a word. The lecture room was often crowded with men from other exercises or laboratories who gathered as standees behind the seats. The same qualities pervaded his clinical teaching, with the added element of sympathetic understanding which endeared him to both patients and students. He illustrated the doctrine that pedagogy is itself an art, an aptitude for which is born in a teacher and which flourishes with intensive cultivation.

Another surgical teacher who left an indelible impress on his students and other contemporaries was Maurice Howe Richardson, who graduated from Harvard College in 1873 and Harvard Medi-

MAURICE HOWE RICHARDSON

cal School in 1877. He was one of the few teachers of the period, of major reputation, who had neither the alleged disadvantage of the background of a legendary Bostonian nor the advantage of study abroad. He was born in rural Massachusetts in 1851 and approached surgery through the portal of the demonstratorship of anatomy, through which so many subsequently able surgeons had passed. He became a surgeon to outpatients at the Massachusetts General Hospital in 1882, visit

ing surgeon in 1886, assistant professor and professor of clinical surgery and finally Moseley Professor of Surgery, succeeding J Collins Warren, in 1907. The prophetic glow of the antiseptic era burst into full dawn as he entered the field, and with his native talent, amounting almost to genius, his industry, his knowledge of anatomy, his imagination and his ambition, he reaped its full benefits. One of his first great feats was the removal of a denture, impacted in the lower esophagus, by opening the stomach, dilating the cardiac orifice and extracting the denture with finger and forceps. This was, of course, long before the favoring help of the x-ray. He promptly took up the surgery of the vermiform appendix as a coadjutor of his medical colleague Fitz, and played an important part in aiding the profession to perfect the diagnosis and to establish the necessity for early operation. His talents as a teacher were not conspicuous in systematic lectures but rather in spontaneous clinical exercises and demonstrations. He was endowed with many talents and with the priceless capital of perfect health. He played the piano, the flute, the 'cello and the bassoon, he swam for pastime across Vineyard Sound, and lest that seemed easy because the water was warm, he swam the nine miles from Salem to Magnolia. He made freehand sketches on the blackboard, often simultaneously with both hands. He had an enormous practice, and about him hung the inspiring aura of success. His death at sixty-one was premature but enviable, with no premonitory attacks of pain or incapacity, he retired one evening with a mind full of plans for an early operation on the morrow, when his failure to appear at breakfast caused investigation he was found lying quite peacefully in bed, with the coverlet thrown off by one unconscious motion of the arm, made as life merged suddenly into death.

The dean of the school and the professor of obstetrics was William Lambert Richardson, who came of old New England stock and was born in Boston and educated at Harvard, where he graduated in medicine in 1867, and then studied in Vienna and Dublin. Always a general medical practitioner, he was one of the first to specialize in obstetrics, which he began to teach in 1871 as instructor, finally becoming professor in 1886. Of great executive capacity, he resuscitated the old Boston Lying-in Hospital, housed in a single brick house on McLean Street, enlarged it by the addition of adjoining houses, established its school of nursing and finally saw it move to the present building on Longwood Avenue, in close proximity to the Harvard Medical School, where the private ward bears his name. He made this hospital one of the great institutions of its kind in the world.

His was a vigorous personality, of swift accurate sagacity, of few and abrupt words but with the qualities of kindness, cheerfulness, optimism and courage which close acquaintance soon recognized. Richardson, early in his career, lost the sight of one eye through an infection occurring while he was attending a patient with puerperal sepsis, the nurse who assisted him at the same critical case suffered the same calamity as her chief. Students will remember the peculiar fixed expression contributed by the glass eye, and will recall also that so little missed his observation that it was commonly said that "Richardson could see more with one eye than most men with two."

Charles Burnham Porter was born of old New England stock in Rutland, Vermont, in 1840, and having graduated from Harvard College and Harvard Medical School and studied in Europe, approached a surgical career in the classic way through long service as demonstrator of anatomy. He passed through the usual steps in the practice and teaching of surgery at the Massachusetts General Hospital and became professor of clinical surgery. As such he conducted clinical exercises at the hospital and conferences based on theses written by students on particular clinical subjects; he also gave a course on operative surgery on the cadaver at the medical school which, as may be guessed, consisted chiefly of amputations, ligation of vessels, resections of joints and incisions. He was a surgeon of the old precise, anatomical, classical school whose flaps were cut exactly according to rule, and who passed the aneurysm needle always in the direction prescribed by the recognized authorities. In his clinical work, however, he did not allow himself to be handicapped by rules but was progressive and original. His instruction was most useful in inculcating the advantage of meticulous care and accuracy. I once heard him say, in discussing his career, that he had never known what it was to feel tired or ill, and his retirement, when forced by the age limit, seemed unfortunately premature yet he died suddenly not very long thereafter.

No account of my surgical teachers could be considered complete without mention of John Homans, who, though not a member of the regular surgical hierarchy of the medical school, gave special lectures on pelvic tumors. He was, it may be supposed, one of the Boston legendary type with all its handicaps, being of the third successive generation of doctors. He graduated from Harvard Medical School in 1862 just in time, after a surgical internship at the Massachusetts General Hospital, to enter the Navy as assistant surgeon, later he transferred to the Army and at an

absurdly young age was surgeon-in-chief of the First Division of the Nineteenth Army Corps and medical inspector on Sheridan's staff at the battles of Winchester and Cedar Creek. Then he studied a while in Vienna and Paris and came back to practice surgery wherever he could find it — at the Boston Dispensary, the Children's Hospital, the

JOHN HOMANS

Carney Hospital and finally at the Massachusetts General Hospital. He pined the fate of women doomed to a life of increasing helplessness and discomfort by the growth of huge ovarian cysts, and encouraged by the success of occasional operators since MacDowell's first operation at Danville, Kentucky, in 1809, and with the safeguards of the new antiseptic method of Lister, he began operating on these patients, first at the Carney Hospital, because the operation was considered by the authorities of the Massachusetts General Hospital to be unjustifiable on account of its danger. Undeafened by early failures and cheered by a rapidly increasing number of successes, he had performed between 1872 and 1900 the prodigious number of over six hundred ovariectomies, as they were called. It will not surprise readers to learn that he had a personality and methods all his own. I remember the final exercises in the course on ovarian tumors which, though occurring in the teaching amphitheater of the medical school, most unexpectedly appeared to be an operation on a living patient. She was wheeled in on a table fully draped ac-

companied by Homans and the assistants in their full surgical costume. It was quite unexpected to see Tom Bonney, technician in the Department of Anatomy, in the role of anesthetist. The incision was apparently made through the skin, subcutaneous tissue, fasciæ, rectus muscles and peritoneum. Hemostatic forceps were applied and retractors introduced disclosing a large cystic tumor which was tapped with a Spencer Welles trocar, its fluid contents evacuated its flaccid sac drawn out of the abdomen and the pedicle ligated and cut away. Then the mounting suspicions of the students were justified by the removal of the sheets and towels, disclosing the patient as a skeleton, in the pelvis of which had been placed a distended pig's bladder and whose abdominal wall had been constructed of suitable layers of fabrics, including red flannel and chamois skin. It sounds like a crude performance and doubtless would scarcely pass muster nowadays, but it was an astonishingly accurate representation of the successive steps of a classic ovariectomy.

Pediatrics was taught our class in the third year by Thomas Morgan Rotch, who justified the characterization as father of modern scientific infant feeding. He was born in New Bedford, but in his veins ran the blood of distinguished medical forebears in Philadelphia. After graduating from Harvard College and from Harvard Medical School in 1874, he served as medical house officer at the Massachusetts General Hospital, studied for two years in Berlin, Vienna and Heidelberg, and on his return joined in turn the staffs of the Boston Dispensary, the Boston City Hospital, the Children's Hospital and the Infants' Hospital. Lectures on "Certain Diseases of Children" had been given by various incumbents of the chairs of medicine before this, but Rotch's lectures on "The Prognosis, Diagnosis and Treatment of Diseases in Children" emphasized the specialized nature of the subject and led to the establishment, at Harvard Medical School, of the first professorship in pediatrics in this country, to which Rotch was appointed first as assistant professor and later, in 1893, as full professor. It was the pioneer department in America — well organized and conducted — and led to the establishment, in 1891, of the first laboratory in the country for the modification of milk for babies. Rotch published his standard textbook on pediatrics in 1895, and wrote monographs on pericarditis and the roentgenology of bones during growth. His campaign for clean milk and other methods to promote safe artificial infant feeding were at first derided and opposed, but he lived to see them adopted. Invalidism in his immediate family and the tragic loss of an only son might have ruined the career of a less

brave man, whose rather gentle and exquisite personality perhaps failed to give the impression of the courage and determination which helped him reach his objectives

A useful man, an important factor in the effective organization of surgical teaching, was Herbert Leslie Burrell, professor of clinical surgery at the Boston City Hospital, without some of the advantages of his colleagues both in pre-medical education and European study, he succeeded by hard work and ability in bringing to the surgical department some attributes which it might otherwise have lacked. He was a born organizer and demonstrator, and supplemented the work of his more showy fellows to the end that the students might have a comprehensive and complete course. He was a close student of the science of surgery, but was somewhat lacking in the instinctive talents which are vouchsafed to some. He performed successfully such unusual operations as ligation of the innominate artery by meticulous preparation and anticipation of every difficulty. He was prominent in many branches of public service, and in the Spanish-American War he transformed an old freighter into a model hospital ship, the *Bay State*, which was inspected and adopted as an example by foreign observers, and in command of which he made three trips to Cuba. The students smiled at his sententiousness and formality and respected his devotion to the work of teaching them. His untimely death revealed that the handicaps of undeclared illness might have thwarted a less determined man.

It is hard to realize that such an important and sharply defined field as neurology was first mapped out by one of the teachers of this era—James Jackson Putnam. He, too, was a legendary Bostonian, a grandson of James Jackson, co-founder of the Massachusetts General Hospital and first professor of clinical medicine. Educated at Harvard and a house officer in 1869 at the Massachusetts General Hospital, he studied in Leipzig and Vienna under Rokitsansky and Meynert and in England under Hughlings Jackson. On his return he began to lecture in 1872 on nervous diseases and established the first neurological clinic at the Massachusetts General Hospital in one small room of the Out Patient Department. He became a leader in this untried field, and for him was created the chair of diseases of the nervous system. His facilities were so meager that he conducted a neuropathological laboratory in his own home, where he made pioneer studies in organic neurology. As a teacher in a rather difficult field for junior students he was not ideal, since his mind ranged so widely over the various related aspects that it was difficult for him to be a clear expositor

of fundamental principles. As he went on he became much interested in the functional neuroses and psychoanalysis and in speculative philosophy, which he pursued with James, Royce and Bergson. His Shattuck Lecture of 1899, entitled "Not the Disease Only, but Also the Man," is a masterpiece of the doctrine suggested by the title. Like most of his race he was a useful citizen—always ready to serve in the charitable and public enterprises of his fellow-citizens. He had the mental qualities of a man of science and a philosopher. His students appreciated the importance of his teaching more in retrospect after they had personally met the problems of neurology in their experience as practitioners.

It is impossible in the brief time at our disposal to acknowledge in full my debt in the matter of my education, but at least brief tribute must be paid to teachers whose stature was no less than those already mentioned, but whose teaching covered lesser fields. James Clarke White, born in Maine in 1833 of vigorous Ulster stock, and educated at Harvard, was a man of versatile intellectuality embracing natural history, literature and art. After graduation in medicine and as house pupil at the Massachusetts General Hospital in 1856, he studied in Vienna, realizing that Paris had passed its heyday as a medical center. On his return he taught chemistry at the school, joined the medical staff of the hospital, noted the neglect of diseases of the skin and cultivated that study with characteristic genius. For him was created the first chair of dermatology in this country, in 1871, which he held for over forty years. He continued his interest in natural history and prepared an herbarium of the wild flowers of New England, he edited the *Boston Medical and Surgical Journal*, he traveled, he cultivated esthetic interests and literature. His constant influence was toward elevating medical education in general and dermatology in particular, and he was one of the group of younger men on whom President Eliot depended for support in his educational reforms. I remember him as tall, erect, vigorous and white-bearded, conducting his skin clinic with military discipline and efficiency. He raised a neglected branch to the dignity of an important special field.

Oliver Fairfield Wadsworth taught me ophthalmology. He was a legendary Bostonian, born in 1838, educated at Harvard and the Massachusetts General Hospital, and saw service as assistant surgeon, Fifth Massachusetts Cavalry, during the Civil War. At its close he studied ophthalmology for two years at Zurich, and on his return became "visiting ophthalmologist to all the hospitals in Boston where there was an eye service." He was a conscientious teacher and a useful citizen, espe-

cially in the medical community. He is said to have been the first to introduce clinical as well as written examinations into the school, he helped organize the Boston Medical Library and was its clerk and secretary for thirty six years. He was an affectionate, disputatious, cheerful man whose modest personality gave all too little opportunity to the students, during a too brief relation to appreciate his worth.

Charles Montraville Green was William L. Richardson's right hand man in the Department of Obstetrics, and long after my school days succeeded to the professorship of obstetrics, with the added field of gynecology. At the turn of the century he was supplementing his chief's lectures by his characteristically well-planned conferences and practical exercises. His summer course in obstetrics, first established in 1880 was famous for its effective organization and success in affording students an experience at least remotely comparable to a service as intern in a lying-in hospital. Green was a lucid, conscientious, painstaking teacher and able clinician whose service to the medical school for thirty odd years and on the staff of the Boston City Hospital for forty four years influenced the education of an army of living pupils.

Edward Hickling Bradford taught orthopedic surgery. Born in Boston in 1848, he was a vigorous scion of Pilgrim stock, a direct descendant of Governor William Bradford. Educated at Harvard College, Harvard Medical School and the Massachusetts General Hospital he studied abroad for two years, and returning joined the surgical staffs of the Boston City Hospital and the Children's Hospital, where the new specialty of orthopedic surgery attracted his interest. Instruction in this branch was confided to him in 1881, and subsequently he became the first professor of orthopedic surgery. He was a man of gentle but forceful personality, characterized by integrity, devotion to his work, fairness and constancy in all his relations. In his early prime a bicycle accident caused the loss of an eye and serious disfigurement, which with characteristic absence of self-pity he refused to permit to handicap him. For six years, beginning when sixty four years of age, he acted as dean of the school, during the trying period which included the World War. When at seventy five his remaining eye gave out, he learned Braille and continued his quiet, unassuming, indomitable service to the community. Another great example of *noblesse oblige* was Bradford.

Clarence John Blake, professor of otology, was one of the first in this country to make a specialty of otology after the invention of the forehead mirror.

was a kind, responsive and ingenious man whose teaching was replete with interest and fascination far beyond the capacity for appreciation of students in an elementary course.

Franz Pfaff exotic, bearded, bespectacled Teuton taught pharmacology with emphasis on the experimental aspect. Frank Winthrop Draper, scholarly, modest hard working, dependable, a veteran of the Civil War, was appointed the first medical examiner of Suffolk County at the time of the abolishment of the old coroner system and taught legal medicine, the while he served the State on the Board of Health, the Boston City and Children's hospitals as visiting physician and organized medicine as secretary, treasurer orator and president of the Massachusetts Medical Society. Davenport in gynecology, Harrington in hygiene, Hills in chemistry and others too numerous to mention (and omitting the names of those still living) played their lesser but important parts in this educational complex.

A comparison of the medical education at the turn of the century with that of forty years later, when I have completed my allotted contribution to the same cause, would be too long a study, but certain outstanding characteristics are perhaps worth emphasizing. The teaching staff was largely recruited from Boston and New England, and indeed from Harvard University itself. None but the pre-clinical laboratory branches were in charge of full-time teachers, whose salaries were modest enough. Most of the teaching staff of professional rank belonged to that group of legendary Bostonians who had in varying degrees the crushing disadvantages of an assured position binding traditions and a competence" before referred to, yet it is my opinion that their teaching bears comparison both in substance and in spirit with that of their successors of today. Forced—or perhaps privileged—as they were to gain their livelihood from private practice, they nevertheless felt a pride and an interest in their academic responsibilities which made it unthinkable that they should slight them. The young physicians whom they educated to go out into the community to heal the sick learned the art from men who were spending their lives in the same pursuit. Fortunate was the school of the turn of the century that its habitat was a community where, in spite of its comparatively slender resources, it could draw its intellectual and spiritual sustenance from citizens whose ideals and standards of education and public duty were those of colonial New England.

INTRA-ABDOMINAL TORSION OF APPENDICES EPIPLOICAE

ROY E. MABREY, MD*

BOSTON

TORSION of an epiploic appendix may give rise to acute abdominal symptoms which result in emergency operations. The diagnosis is difficult and is rarely made. The first 16 cases reported in the literature were abstracted by Hunt¹ in 1919. He gave a general discussion of the subject, and included abstracts of cases of appendices epiploicae acting as foreign bodies and also their relation to hernias.

In 1936 Fiske² reviewed the literature and found 26 additional cases, making a total of 42. He added 2 cases from his clinic, in both of which a correct preoperative diagnosis was recorded. Since his article appeared 2 other cases have been reported,³ making a total to date of 46 recorded cases.

Appendices epiploicae are small pouches of peritoneum filled with fat, and are found in one or two rows along the large intestine. On the ascending and descending portions they are located medially, while on the transverse colon they are on the lower part. They are pedunculated and are supplied with small arteries and veins. Their function is not known. They act as a storage place for fat, and they may also facilitate the motion of the large bowel by acting as skids or cushions.

Disease of these structures is very limited. The commonest lesion is twisting of the pedicle with resulting infarction. Infarction, gangrene and strangulation are terms encountered in this connection. The necrotic tab may, perhaps, by becoming attached to the bowel wall give rise to severe cramp-like pain.

The onset of symptoms in cases of infarction is usually sudden and without an obvious predisposing cause. Most frequently the pain is generalized but may become localized. It is sometimes associated with nausea and vomiting. The portions of large bowel involved are about equally divided between sigmoid and cecum.

On examination the patient does not appear ill. He may show signs of discomfort from steady aching or peristaltic pain. Rectal examination may show tenderness on one or both sides. The temperature is only slightly elevated, if at all, but the white blood-cell count may reach 20,000.

Diagnosis is difficult. The entire picture when the pain is on the right side is impossible to distinguish from that of a mild attack of appendicitis.

Among the diagnoses made preoperatively have been cholecystitis, ovarian cyst with twisted pedicle, renal calculus, diverticulitis and intestinal obstruction. When the lesion is on the left side it is more easily recognizable.

Treatment is removal of the necrotic mass after ligating its base, and careful inspection of the bowel wall in order to see that no perforation exists. In one case the mass was left in because of inaccessibility. The patient continued to have pain, spasm and tenderness for ten days.

I have recently seen a patient (Case 6) on whom a preoperative diagnosis of subsiding appendicitis was made but at whose operation a necrotic twisted epiploic appendix was found. In order to determine the frequency of occurrence of this condition I have examined the case records of the Massachusetts General Hospital and have found only 5 other cases. In none of these was a correct diagnosis made.

CASE 1 (W. S. 175356) The patient, a 36-year-old man, was admitted April 4, 1911. Twenty-four hours previously he had developed sudden severe pain in the right lower quadrant of the abdomen. There was no radiation and no nausea or vomiting. The patient went to bed and applied an ice bag. He had chills and fever all day.

Examination on admission showed slight spasm in the right upper quadrant. There was marked spasm in the right lower quadrant, with some tenderness. No masses were felt. The temperature was 99°F, the pulse 62, the respirations 20, and the white-cell count 12,600. The urine was normal.

The preoperative diagnosis was appendicitis. At operation a necrotic mass the size of a small apple was found on the cecum. This was removed and an appendectomy was performed. The pathological laboratory reported peri-appendicitis and infarction of an epiploic appendix.

CASE 2 (E. S. 193799) The patient, a 28-year-old woman, was admitted February 19, 1914. She had had an attack of pain in the bladder region 16 years previously, of 5 days duration. Four months later she had fever, accompanied by pain in the left upper quadrant of the abdomen, for 2 weeks. There was some nausea and vomiting. Several subsequent attacks of pain in the abdomen occurred, coming at night and lasting for 1 hour. Three days before admission the patient was awakened by pain in the right lower quadrant. There was no radiation, but the pain was severe enough to double her up. It gradually diminished but fluctuated in intensity. There was no nausea or vomiting.

Examination revealed a round, soft, tympanic abdomen. There was marked tenderness in the left flank and slight tenderness in the right lower quadrant. No masses and no spasm were felt. An appendectomy was per-

formed and a calcareous epiploic appendix was removed from the sigmoid. The pathological laboratory reported chronic appendicitis and gangrene of an epiploic appendix.

CASE 3 (E. S. 196336) The patient a 32-year-old man was admitted June 30, 1914. About 24 hours previously he had begun to have sharp pain throughout the lower abdomen. This lasted about 2 hours and was accompanied by nausea and vomiting. He went to work the following day but had another attack in the afternoon lasting 1 hour. A few hours later he had a third attack, which was more severe than the previous two. It was characterized by severe knife-like pain in the right lower quadrant of the abdomen.

Examination revealed a soft, tympanitic abdomen. There was no spasm or rigidity. There was tenderness in

cus. There was some tenseness of the muscles. The rectal and pelvic examinations were negative. The temperature was 98.6 F., the pulse 86 and the white-cell count 10,200. The urine was normal. The preoperative diagnosis was acute appendicitis.

At operation a strangulated epiploic appendix was found over the base of the vermiform appendix. Both were removed. The postoperative diagnosis was infarction of an epiploic appendix.

CASE 5 (E. S. 14999) The patient a 46-year-old man was admitted January 27, 1937 complaining of generalized abdominal pain of 30 hours duration. There was no nausea or vomiting but the patient could not eat because of persistent abdominal cramps. He took a tablespoonful of castor oil and was awakened in the night with generalized cramps. A second dose was followed in

TABLE 1 Summary of Clinical Data

| CASE NO. | AGE | SEX | LOCALITY | ONSET | OTHER SYMPTOMS | TEMP. F. | WHITE CELL COUNT $\times 10^3$ | LOC. SIG. | PREOPERATIVE DIAGNOSIS | LOCATION OF LESION | TREATMENT | RESULTS |
|----------|-----|-----|-------------|-------|----------------|----------|--------------------------------|------------------------------|--|-------------------------------------|---|--|
| 1 | 31 | M | R. L. Q. | 24 hr | Chills | 99.4 | 12.6 | Spasm | Appendicitis | Cecum | Appendectomy and removal of epiploic appendix | Relieved |
| 2 | 28 | F | R. L. Q. | 16 hr | No vomiting | 99.4 | — | Tenderness | Appendicitis | Sigmoid | Appendectomy and removal of epiploic appendix | Relieved |
| 3 | 32 | M | Generalized | 28 hr | No vomiting | 99.4 | 70.0 | Tenderness (R. L. Q.) | Appendicitis | Sigmoid | Laparotomy | Pain and tenderness with mass in left lower quadrant, for 10 days. |
| 4 | 57 | F | R. L. Q. | 24 hr | None | 98.6 | 10.1 | Tenderness (R. L. Q.) | Appendicitis | Cecum | Appendectomy and removal of epiploic appendix | Relieved |
| 5 | 40 | M | General | 30 hr | None | 99.5 | 15.2 | Tenderness (R. L. Q.) | Intestinal obstruction, diverticulitis, appendicitis | Attached to ileum (origin doubtful) | Removal of necrotic mass adherent to ileum | Relieved |
| 6 | 70 | M | L. L. Q. | 30 hr | None | 99.2 | 11.2 | Tenderness, spasm (L. L. Q.) | Appendicitis | Sigmoid | Appendectomy and removal of epiploic appendix | Relieved |

the left lower quadrant. There was also some pain over McBurney's point. No masses were felt. Rectal examination showed tenderness on both sides. The temperature was 99.2 F. the pulse 100 the respirations 20 and the white-cell count 20,000. The preoperative diagnosis was acute appendicitis.

Exploration revealed a slight kink in the vermiform appendix but no inflammation and an inflamed infiltrated mass attached to the sigmoid. Because of its inaccessibility it was not removed. An appendectomy was performed. The postoperative diagnosis was strangulated epiploic appendix. The patient continued to have pain with some spasm in the left lower quadrant for 10 days.

CASE 4 (W. S. 305485) The patient, a 57-year-old woman was admitted January 18, 1935 complaining of soreness in the right lower quadrant of the abdomen. This had come on suddenly about 24 hours before entry. She took a laxative and had two small bowel movements without any increase in pain. There was no nausea and no urinary symptoms. The pain persisted but was not severe enough to keep her awake or interfere with her appetite.

On examination the abdomen was pendulous and there was a tender point to the right of and below the umbilicus.

7 hours by a profuse bowel movement, the first in 2 days. The cramps persisted and the patient was admitted to the hospital.

On examination the abdomen was soft. There was some distention of the cecum and ascending colon. There was no mass or spasm. There was localized tenderness in the right lower quadrant. Rectal examination showed tenderness high on both sides. The temperature was 99.5 F. and the white-cell count 15,200. The urine was normal. The preoperative diagnosis was possible partial obstruction, possible diverticulitis and possible acute appendicitis.

Exploration showed the vermiform appendix to be normal. On freeing the cecum a loop of ileum was brought up and a piece of hemorrhagic tissue measuring 3 by 4 cm was found attached to it. It had apparently become separated from the colon and attached itself to the ileum. It was readily freed and the wound was closed without drainage after removal of the appendix. The pathological laboratory reported infarction of an epiploic appendix and periappendiceal hemorrhage.

CASE 6 (private case) The patient, a 20-year-old man was seen January 17, 1938. He had been perfectly well until 30 hours previously when after eating a small bur-

ried lunch he immediately felt a dull pain in the left lower quadrant of the abdomen. This persisted through the night and gradually became worse. The pain was not severe enough to double him up but was enough to make him consult his physician. There was no nausea, vomiting, urinary disturbance, change in bowel habits or melena. The patient had had no previous similar attacks. The past history was negative except for removal of a semilunar cartilage 1 year previously.

Examination revealed a well-developed and healthy appearing man. The abdomen was flat. There was slight tenderness over McBurney's point. In the left lower quadrant there was marked tenderness with muscular spasm. There was also slight spasm in the right lower quadrant. There was no pain on leg raising, but some pain on the left with hyperextension of the right leg. Rectal examination showed some tenderness on both sides, but it was more marked on the left. There was some fecal material in the rectum. The urine was normal. The temperature was 99.2°F, the pulse 84, the respirations 20, and the white-cell count 11,000.

It was thought that appendicitis was likely, although the symptoms were somewhat atypical, and the patient was admitted. An enema caused some pain and was discontinued. The white-cell count a few hours later was 9600. The following day the enema was repeated with less discomfort. The white-cell count dropped to 6300, and the pain and tenderness were much less marked. A flat x-ray film of the abdomen was negative. In the afternoon the pain and tenderness increased and the pain became peristaltic in character. A barium enema was given. There was some pain when the colon was partially filled, but spasm and diverticula were not demonstrated. The appendix was not seen. The patient was then given a motor meal and x-ray photographs were taken at intervals. No Meckel's diverticulum was seen. The appendix was visualized and was seen to contain many fecoliths. In view of the fact that the patient was employed on a ship, it was decided to explore the abdomen.

On opening the peritoneum a firm nodule measuring about 2 by 2 cm was felt in close relation to the sigmoid. It was delivered without difficulty and found to be a gangrenous epiploic appendix. It had become twisted on its pedicle and was adherent to the sigmoid. This mass was freed and its pedicle ligated and excised. There were some adhesions around the cecum. A kinked and thickened vermiform appendix was removed.

Convalescence was uneventful, and there has been no recurrence of symptoms.

Presentation of 6 additional cases of torsion of appendices epiploicae brings the total reported to 52. There were 29 men and 23 women. The age incidence varied from twenty to seventy, the average age of this series is thirty-five. In the published cases there were 5 in whom the condition was an incidental finding. In the others,

acute symptoms were present which necessitated operation.

Pain is the commonest symptom. It is usually sudden in onset and varies from moderate to severe. It is often peristaltic in character. Localized tenderness may be present, with or without spasm. The temperature is slightly elevated, and the white-cell count may reach 20,000.

There were 6 deaths in the cases reported in the literature. In 2 of these the torsion was an incidental finding at autopsy, 1 patient having died of acute hemorrhagic pancreatitis and 1 of cardiac failure. In 4 cases, however, death was definitely related to torsion of an epiploic appendix. In 1 case reported by Riedel⁴ the patient had intestinal obstruction and died from peritonitis the day after operation. In Ebner's⁵ case death occurred on the seventh postoperative day and was due to paralytic ileus secondary to interference with the blood supply from the torsion. Seelye⁶ reports a death due to generalized peritonitis a few days after drainage of an abscess caused by a twisted gangrenous epiploic appendix. Baumeister, Hargens and Morsman⁷ report a death from intestinal obstruction due to adhesions between appendices epiploicae.

SUMMARY AND CONCLUSION

Only 46 cases of torsion of an epiploic appendix have been reported.

The symptoms and signs of appendicitis are closely simulated.

The preoperative diagnosis is rarely made.

Six additional cases are summarized.

Vague abdominal pain is probably often due to an unrecognized strangulated epiploic appendix.

LUNG ABSCESS*

DONALD D. MATSON

BOSTON

ANY disease which is chiefly a complication of other medical and surgical conditions, and therefore presumably in some measure controllable by the management of those conditions, deserves exhaustive investigation, especially when the disease still gives rise to a reported mortality in treated cases of 30 to 50 per cent.^{1-9, 22-27}

Diagnosis of nontuberculous abscess of the lung is relatively simple. It is rather a problem of treatment and, even more significantly, of prevention. Intelligent treatment is based on an accurate understanding of the pathology and the pathologic physiology involved, and any program of prophylaxis must presume some knowledge of etiology, bacteriology and precipitating incidents.

ETIOLOGY

There are three possible pathways of infection to the lung parenchyma besides direct contamination incident to trauma. These are the trachea and bronchial tree, the blood stream and the lymphatics. It seems fairly certain that the lymphatic route must be rare, though occasionally it may be of significance in bringing infection from a focus in surrounding tissue. That infection frequently reaches the parenchyma through the bronchi is generally conceded, and it seems probable that it is carried there by the blood stream more often than is clinically suspected.

Cutler and his associates¹⁰⁻¹¹ found many years ago that they could produce lung abscess in dogs by releasing in the venous circulation an embolus consisting of a small section of a tiny vein filled with organisms. Their findings led them to believe that embolism from the operative wound and local immune reactions in the lung were the important factors in postoperative lung abscess. Feterolf and Fox¹² studied tonsillectomy wounds in dogs and found hemorrhages, thrombi, necroses and bacteria present in the surrounding tissue. Because the muscular pharynx can never be put at rest, they believed that thrombi were readily discharged, resulting in pulmonary infarcts which subsequently became infected with organisms from the upper respiratory tract. Many of these pulmonary infarcts probably escape notice because of

their small size, sterile character and prompt resolution. Castleman⁶ and Hampton¹³ on the basis of correlated postmortem x-ray and anatomical studies, have expressed the belief that incomplete pulmonary infarction is much more frequent than was previously suspected.

Recent investigators have been able to produce lung abscess readily by injecting infected material into the bronchi. Weiss¹⁴ for instance, has done it repeatedly in monkeys by inserting a mixture of agar and anaerobic organisms obtained from lung abscesses at operation into the bronchus of the left lower lobe. His evidence suggests that aspiration of infected material, together with plugging of the bronchus, is responsible for abscess formation.

Clinically it is often impossible to establish whether an embolus or aspiration is the origin, but it seems probable that the latter route is usually responsible. The bacteriological flora of a well developed abscess is qualitatively very similar to that of the unhygienic oral cavity. It is difficult to see how a septic embolus, from a laparotomy wound, for instance, could give rise to this picture in itself. Where emboli are involved, a sterile or simple primarily infected infarct probably results, and this is secondarily infected by a complication of buccal organisms.

In analyzing the cases of lung abscess at the Boston City Hospital, Freedman¹⁵ concluded that pulmonary atelectasis was the important factor in stagnation of infected material in shut-off portions of the lung. He found that chronic pulmonary conditions such as bronchitis, asthma and bronchiectasis provided fertile soil for acute suppuration. Apparently there must be a primary lesion of some kind in the lung before secondary infection by mouth organisms can take place. This lesion may be due to infarction as a result of an embolus, or atelectasis due to bronchostenosis or obstruction by plugs of secretion. The normal bronchial tree is admirably equipped by its secretions, cilia and reflex cough mechanism to handle the organisms which must constantly descend from the upper respiratory tract, but when this process is disrupted by mechanical factors incident to disease or surgical manipulation, infection is liable to ensue.

PATHOGENESIS

The numerous series of cases of lung abscess reported in the literature all show that the majority of cases follow operations on the upper respiratory tract and pneumonia. Of the 276 cases reported by Freedman,¹⁵ 196 were sequelae of medical conditions and 76 followed operative procedures. The medical causes included pneumonia, chronic cough, influenza, tuberculosis and carcinoma. A large percentage of these cases could ultimately be traced back to the common cold or some other acute process with an intervening atelectasis in the lung. Great numbers of these patients were in poor general condition owing to alcoholism, diabetes or cardiac or peripheral vascular disease, and poor oral hygiene was practically universal. The incidence of lung abscess as a postoperative complication of various operations in this series is shown by the following ratios:

| TYPE OF OPERATION | RATIO |
|---------------------------------|--------------------------|
| Tonsillectomy and adenoidectomy | 1 1654 (1 626 in adults) |
| Tooth extraction | 1 320 |
| Appendectomy | 1 1411 |
| Pelvic surgery | 1 774 |
| Gastric surgery | 1 54 |
| Gall-bladder surgery | 1 258 |

The high incidence of this condition following operations on the upper abdomen, namely the stomach and gall bladder, is especially interesting because it is also true of atelectasis, massive collapse, embolism and other postoperative pulmonary complications.²¹

Of the cases of lung abscess at the Massachusetts General Hospital reported by King and Lord,²² 56 per cent followed operations on the upper respiratory tract and 9 per cent other operations, 23 per cent were insidious in onset, and 8 per cent had a stormy onset following pneumonia. In a series reported from Toronto,³⁷ 30 per cent followed upper respiratory operations, 19 per cent followed pneumonia, 7 per cent were associated with definite pulmonary emboli and 33 per cent were classed as idiopathic. These percentages are representative of many reported series.

The etiologic factors in cases in children have a somewhat different proportion. On examining records of the cases diagnosed as lung abscess at the Boston Children's Hospital during the ten years previous to 1938, it was found that 53 per cent followed tonsillectomy but none followed any other operations, 6 per cent followed the aspiration of foreign bodies and all the rest developed from unresolved pneumonia or severe upper respiratory infection. In all these cases in children it was possible to find some definite precipitating incident. This is a very interesting fact. The bacterio-

logical flora of the buccal cavities of children under ten differs from that of adults in that fusiform bacilli and spirochetes are rarely found and staphylococci are more prevalent.²⁴ In children, oral hygiene is much better and the severe gingivodental infections of the adult ward patient are rare.

Stern,³⁶ at the Mount Sinai Hospital in New York, examined all the cases of lung abscess in which the etiology was unknown, and found that 84 per cent presented a typical and uniform picture of marked dental disease with infected gums and large masses of dental tartar. It is in dental tartar that anaerobic organisms thrive. The tartar when aspirated, Stern believes, acts as an irritating foreign body and therefore facilitates the development of lung suppuration in the presence of infecting organisms. His observations seem sufficiently well controlled to permit the conclusion that oral disease is disproportionately common in patients with abscess of the lung of unknown etiology. Neuhof³⁰ found gross gingivodental infection in 17 of 26 cases of lung abscess of unknown etiology, and pointed out that among the children in his series where this type of infection was not present there were no cases of unknown etiology. There are other reports³⁹ with the same clinical impression, so that it seems probable that many cases of so-called idiopathic abscess are due to inhalation of infected material from badly diseased teeth and gums.

In many cases it is difficult, if not impossible, to determine whether a sudden illness is due to an abscess proper or to a pneumonic condition with subsequent abscess formation. The roentgenologist may not be sure about the consolidation he first sees, and physical signs, if present at all, are not diagnostic. It is the patchy bronchopneumonia of the influenza type that seems particularly prone to give rise to lung abscess.

Lung abscesses due to the aspiration of foreign bodies usually occur in children, and need no comment here, except to call attention to the interesting observation in a British journal²² that the probable reason why these cases are so much commoner in the United States than in England is the popularity in this country of chewing gum and peanuts.

PATHOLOGY

Single lung abscesses are generally located in the right lung. This is also true, however, of other pulmonary lesions such as embolism and lobar pneumonia. The more direct continuity of the right primary bronchus with the trachea is of interest in this regard. Also the right branch of the pulmonary artery is slightly larger and is said to

come off more directly from the bifurcation, and the right lung itself, of course, is larger than the left.

Most abscesses are situated at the periphery of the lung and the overlying pleura very early shows clouding and thickening. Neuhof²⁰ believes that even in the early acute stage pleural adhesions are present. He describes the lesion as at first an intense necrotizing inflammation of the affected bronchioles with rapid destruction of lung tissue, resulting in cavitation with contained pus and detritus. Others believe that there is first an area of diffuse pneumonitis, which either resolves of itself or undergoes necrosis, liquefaction and cavity formation.^{1, 22, 24} Either of these processes is in contrast to that stimulated by the tubercle bacillus which is essentially fibrosis. If the abscess is recent and progressing, its wall consists of soft, necrotic lung tissue surrounded by edema and hyperemia. The dense rind of the abscess by x-ray, frequently described as fibrosis, melts away so completely under satisfactory treatment that it must be exudative.²²

Single abscesses are usually round and contain thick, yellowish or greenish pus, which may or may not be blood streaked. It may be odorless, sweet or foul, depending on the particular organisms present. If the cavity can be successfully drained, it may be obliterated except for a thin, fibrous scar. On the other hand, if chronic pulmonary suppuration and gangrene ensue, the sputum is apt to become thin, gray or brownish green and intensely foul, and in that event usually reveals fusiform bacilli and spirochetes in large numbers. There is progressive ulceration of lung tissue so that the characteristic lesion is ragged, with an advancing periphery and enlarging cavities filled with necrotic lung, exudate and innumerable bacteria. Patients with these lesions die from absorption of bacterial toxins if they survive any attempted operative procedures and escape such complications as massive hemorrhage, metastatic brain abscess and meningitis. They may drown in their own pus owing to the rapid bronchiogenic spread of the disease.

BACTERIOLOGY

In lung abscess, as in spreading peritonitis following perforation of the bowel, there is usually more than one organism present and the flora may be very complex. The bacteria found in any case depend on whether material is smeared or cultured from the sputum, from pus obtained bronchoscopically or from pus obtained directly from the abscess cavity at operation. Bucher³ cultured pus obtained bronchoscopically from 118 cases and found the following organisms predominant:

| ORGANISM | NO. OF CASES |
|--------------------------------|--------------|
| Streptococci (all varieties) | 93 |
| <i>Micrococcus catarrhalis</i> | 61 |
| Pneumococci | 50 |
| <i>Haemophilus influenzae</i> | 41 |
| <i>Staphylococcus albus</i> | 39 |
| <i>Staphylococcus aureus</i> | 22 |
| Diphtheroids | 29 |
| Spirochetes | 25 |
| Fusiform bacilli | 25 |
| <i>Micrococcus tetragenus</i> | 22 |

He cultured 20 of these anaerobically and found 14 positive for streptococci. Cohen⁴ found anaerobic streptococci in all 16 cases cultured at operation, and in 14 of these he found *Bacillus melanogenicum*. The latter organism has also been widely cultured recently from cases of peritonitis and has been thought² to be the agent responsible for the fetid odor. Neuhof and Wessler²⁴ believe that all putrid abscesses are initiated and certainly maintained by pathogenic anaerobes. They state that they can be found at every stage of the infection and disappear when the infection subsides. Supporting the pathogenicity of these organisms is the work of Cohen,⁴ who found that washed filtrates of 80 per cent of anaerobic gram negative bacilli obtained from lung abscesses at operation gave a positive Shwartzman reaction. Only with organisms giving this reaction was he able to produce severe necrotic lesions in the lungs of rabbits.

There really is no need to postulate a single bacteriologic etiology. We know that many types of organisms give rise to pneumonia, for instance. Possibly the original infecting agent has no clinical significance other than producing the minor lesion in the lung which paves the way for secondary invaders which are in turn responsible for the characters of the full-blown abscess. Possibly it is the quantitative relation between these various secondary organisms that is responsible for differences seen in the clinical picture and course of the disease in various patients. The importance of the synergistic action of various combinations of bacteria we know very little about. From the work of Meleney, Olpp, Harvey and Jero²⁷ and others on the bacteriology of peritonitis it seems probable that synergism often enhances remarkably the pathogenicity of given organisms in the body. The importance of the various types of fungi frequently found is also little understood.

DIAGNOSIS

The clinical picture is so well known that it is necessary here only to recall the typical onset, one to three weeks following operation or pneumonia, of cough, at first dry and then productive of sputum which may or may not be foul and may or may not be blood streaked. There may be dysp-

nea, cyanosis or chest pain of a pleural nature, or these may all be absent. A rise in temperature with general malaise and weakness is a fairly constant finding. Physical examination is seldom of much aid early in the course of the disease. Localized signs in the chest vary according to the size and content of the cavity and the amount of surrounding exudation. Fever, leukocytosis and other constitutional signs of sepsis are present. There may be clubbing of the fingers.

The picture at any one point in the course of the disease depends primarily on the adequacy of drainage, whether by the bronchus or through a surgically created tract. If drainage becomes inadequate the temperature and white-cell count rise, weakness becomes more marked and the patient appears to be losing ground until drainage is re-established.

X-ray examination may show a characteristic single localized abscess cavity with a fluid level, surrounded by a narrow margin of pulmonary infiltration, or the cavity may be filled so that its shadow merges with that of the surrounding exudation in the lung. X-ray examination in the upright position is essential to the demonstration of fluid levels. The abscess may be masked by the simultaneous presence of empyema. While x-ray examination may be important for primary diagnosis, it is of even greater significance in accurate localization of the abscess, which is so necessary for satisfactory postural or surgical drainage. Stereoscopic films and films taken in three planes are invaluable to this end. Sometimes visualization of the bronchial tree by Lipiodol gives the most accurate picture, although it is notably difficult to introduce Lipiodol into an abscess cavity by way of the bronchi. X-ray examination is also of great aid in following the course of the disease, estimating the adequacy of drainage and helping to decide when surgery should be instituted.

Another aid to diagnostic localization is bronchoscopy. When it is skillfully performed, the exact bronchopulmonary segment from which pus is coming can be located in almost every case. Bronchoscopy is all-important where a foreign body or tumor is suspected, and as an aid in evaluating the cause of impaired bronchial drainage.³⁴

TREATMENT

No program of therapy can be outlined which is more than generally applicable, and at present it seems probable that the ultimate result depends less on the choice of method of treatment than on the thoroughness and intelligence with which the method selected is carried out. However, some systematic plan, labile enough to fit the demands and complications of the particular case, should be

adopted. The internist and the surgeon must work together from the beginning, because the rational treatment of lung abscess involves the methods and judgment of both. Every case should have a trial of medical therapy before surgery is instituted, but the surgeon should follow the case with the internist during this period.

Of 2114 cases collected from the literature by Allen and Blackman,¹ 51 per cent were treated conservatively and 49 per cent came to some type of surgical procedure. The mortalities in these two groups are almost identical, 34.4 and 34.2 per cent. The difference in the type of the cases in the groups should be remembered. It is doubtful whether any lung abscess heals without the establishment of good drainage. This may be accomplished, however, by spontaneous rupture into a large bronchus as well as by various medical and surgical procedures. This appears to be particularly true in children. One third of the cases diagnosed as lung abscess on the basis of cavitation by x-ray at the Children's Hospital cleared with only conservative therapy in two or three months, and most of these were symptom-free after six weeks' observation. This high percentage suggests that there are many more cases of mild lung abscess which clear up spontaneously at home and never get diagnosed. Graham, Singer and Ballou¹⁸ hold the same view as to adults, believing that almost every patient with streptococcal pneumonia has some small abscesses. In adult series probably 1 case in 5 heals spontaneously. Expectation for this type of recovery is largely confined to patients with a short previous duration of the disease. The exciting cause of the abscess appears to be of no significance.

What is the proper medical treatment of lung abscess? Besides complete bed rest, a high-vitamin, high-caloric diet, adequate fluids and pleasant surroundings, the importance of all of which cannot be overestimated, medical measures include postural drainage, bronchoscopic drainage, pneumothorax, the giving of arsenic and guaiacol and symptomatic drug therapy. The regimen should be as strict as that of pulmonary tuberculosis, and cases which respond should receive hospital or sanatorium care for considerable periods after they have become symptom-free. This step is only too often neglected, with a discouraging recurrence of the lesion.

Postural drainage is the most important single procedure. In order to be of value, it must be carefully and faithfully carried out. The exact location of the abscess must be determined, so that the best position for drainage can be assured. "Posturing" is usually advocated for fifteen or twenty minutes three or four times a day. It is

not infrequent to obtain 300 or 400 cc. of pus per day by this method. Continuous postural drainage is too uncomfortable. It must be remembered that it is frequently a great physical effort to get the pus out, and what the patient may need most of all is rest.

The place of the bronchoscope in the treatment of lung abscess is not yet definitely established. It is of the greatest value where a foreign body or bronchostenosis due to some other cause is present. Obstruction due to inspissated secretion can readily be relieved. In cases of inoperable bronchiogenic carcinoma with associated abscess it is justifiable to employ bronchoscopic drainage of the abscess because of the distressing symptomatology. The instrument may be passed as often as two or three times a week without undue inflammatory reaction of the bronchial mucosa.⁴⁴

Pneumothorax has been practically discarded in the treatment of abscess because of the danger of producing empyema, and because it has generally been disappointing as a means of closing cavities. It is not nearly so effective in this respect as it is in tuberculosis, and more than 50 per cent of cases require further surgery.⁴⁵ It is indicated only in cases where the cavity is adequately drained centrally by a bronchus, yet does not collapse satisfactorily. If compression therapy is attempted when adequate drainage has not been established, the patient may rapidly drown in his own pus. Also it must be remembered that the cough is the body's most efficient means of expelling undesirable material from the upper respiratory tract, and anything which interferes with intrathoracic compression, and therefore with coughing, handicaps drainage.⁴⁶

Arsphenamine and related compounds appear to be of value only in cases in which there is a copious growth of spirochetes, and even here the results are not very striking. It seems probable that small intravenous doses of neosarsphenamine regularly repeated may prevent the loss of lung tissue due to secondary spirochetal invasion, but is doubtful if it has any effect in healing the abscess itself.^{47 48 49}

Nammack and Tiber⁵⁰ have reported the cure of 16 of 20 selected cases treated intravenously with guaiacol, Guaiacol, creosote and related compounds have long been known to be of some value in the treatment of the secondary invaders in pulmonary tuberculosis. When this material is injected intravenously with sodium iodide in a dilute alcoholic solution, it is recovered in the sputum or in the drainage from the operative wound during the first forty-eight to seventy-two hours. The patients in this series are reported to have felt better a short time after the administration of the

drug was started, owing to subsidence of fever and cough and decrease in the daily output of foul sputum.

What are the indications for surgical intervention and what does the surgeon have to offer? In reporting cases from the Peter Bent Brigham Hospital, Cutler and Gross⁵¹ state that the mortality could probably be lowered if all cases were submitted to early surgical drainage, but that many patients would then be operated on who would have recovered spontaneously. General opinion has held that six weeks to two months of active medical therapy should be tried, and this treatment prolonged if significant improvement occurs. Neuhoof,^{52 53} in New York City, holds a more radical view, believing that abscesses should be operated on in the acute stage, that is in less than six weeks, if they are not progressing satisfactorily. He reports losing only 4 out of 45 consecutive cases operated on in the acute stage.

The surgeon has at his disposal various compression operations, one-stage or two-stage external drainage and lobectomy and pneumonectomy. Phrenicectomy, extrapleural pneumolysis and thoracoplasty have all been used, but like artificial pneumothorax have been unsatisfactory and generally abandoned because of the danger of empyema and of a drowned lung resulting from collapse in the absence of adequate central drainage. These operations may be indicated in deeply situated abscesses communicating with a large bronchus, draining well and unlikely to rupture into the pleural cavity. However, such an abscess must be extremely rare, and is likely to heal spontaneously if central drainage is maintained.

Rib resection with external drainage is indicated when the abscess is at the periphery of the lung. Here the abscess drains poorly into the bronchi and is likely to rupture into the pleural cavity. There is little normal lung over the abscess, so that the danger of pneumonia and hemorrhage from operation is minimal. A one-stage operation is indicated when there are well formed overlying pleural adhesions. Neuhoof⁵⁴ believes that with any peripheral abscess agglutinating adhesions of the two pleural surfaces occur very early usually within two weeks, and that the important thing then is to find them. He claims to have found overlying adhesions in every one of his cases no matter how early he operated though not always where he first looked for them. Most surgeons, however, have thought that during the early stages of the disease, while adhesions may be present, they do not entirely obliterate the pleural cavity, so that a one-stage procedure is not suitable. When adequate adhesions are not present a two-stage operation is in

licated, the first stage of which is done in order to create such adhesions by sewing the pleural layers together, packing gauze against the pleura or by some other means. The second stage, then, usually performed by cautery excision, consists in unroofing the abscess cavity and packing it thoroughly. Bronchial fistulas are always seen at operation, and in the subsequent treatment should be allowed to close only after all evidence of anaerobic infection is gone and infiltration is no longer present as shown by x-ray, a matter usually of at least six to eight weeks, and often some months.

A ruptured abscess with pyopneumothorax demands immediate drainage, and the prognosis in that event is usually graver than otherwise. Diagnostic or therapeutic needling of the lung abscess should be avoided because of the possibility of contamination of nonadherent pleural surfaces.

Lobectomy and total pneumonectomy are the newest weapons of the thoracic surgeon. These radical procedures are not well suited to acute suppurative lesions, because the presence of active infection makes bronchopleural fistula, empyema and other complications common. In carefully selected cases, however, one of these methods can be used, and indications for this type of surgery are being rapidly extended.

It is not possible at present to tell which cases of lung abscess are proceeding on to chronic pulmonary suppuration and gangrene.²⁵ The cases at the Children's Hospital were examined with this in mind, but aside from the time factor nothing significant was apparent. If healing by conservative means is going to occur at all, it seems to do so in the first six weeks. Abscesses which fail to resolve within this time probably will never do so, and the early use of radical surgery may then be indicated. Any correlation between the bacteriology of the sputum first obtained and the future course of the disease was not discernible because of insufficient bacteriological data. It was impossible in the postoperative cases to find out what sort of condition the child was in at the time of the operation, since it was performed in another hospital or at home. Postoperative lung abscesses are rarely treated in the same clinic in which the original operation was performed.

The etiology of the abscess in these cases apparently had no effect on the ultimate outcome. About one third of them resolved spontaneously, one third were improved or cured by surgical procedures and one third resulted in death, either from acute overwhelming sepsis or from chronic suppuration which did not respond to surgery.

PREVENTION

Can anything be done to lower the incidence of lung abscess? The measures of recognized importance in the prevention of all postoperative pulmonary complications should be rigidly observed. These are, essentially, reduction of trauma to a minimum, careful hemostasis, careful control of sepsis and, most important of all, extreme caution in operating on patients with any predisposition to atelectasis or formation of mucus.¹⁰ To these we might add certain measures of probable significance in lessening the aspiration of infected material. Oral and dental hygiene should receive exact evaluation, and gingivodental infections be treated before any elective surgery is undertaken. Tonsillectomy and other operations on the upper respiratory tract must be considered as major surgical procedures and should be performed in a hospital. This is especially true in adults, where tonsillectomy should be performed only with definite indications. Teeth should be extracted in several sessions and where possible under local anesthesia. Interference with lung ventilation during and after operation should be closely watched for, and atelectasis resulting from mucous plugs relieved immediately by aspiration. A self-evident prophylactic measure is the adequate early treatment of pneumonia and other severe upper respiratory infections.

SUMMARY AND CONCLUSIONS

The majority of cases of nontuberculous abscess of the lung follow operative procedures of the upper respiratory tract or develop subsequent to unresolved pneumonia or other severe upper respiratory infections.

A primary lesion in the lung is apparently present before secondary infection with mouth organisms takes place, this may be infarction as a result of embolism or atelectasis as a result of bronchostenosis or bronchiolar obstruction.

There is no single bacteriologic etiology. The flora of the full-blown abscess is usually complex, and the quantitative importance and possible synergism of the various organisms are not at present understood.

It appears that oral infection is disproportionately common in adult patients with lung abscess of unknown etiology. This type of abscess is rare in infants and children.

The diagnosis of lung abscess is usually readily made from the history and general clinical picture, aided by roentgenography and bronchoscopy. The physical findings in the chest may be variable and inconclusive.

Accurate diagnostic localization is the most im-

portant prerequisite to both medical and surgical treatment

Twenty to 30 per cent of cases heal with only supportive treatment, and all cases should receive an adequate trial of medical therapy, of which the most important feature is supervised postural drainage.

Collapse therapy, either by pneumothorax or by more extensive operative procedures, should never be attempted unless the abscess cavity has been adequately drained

In peripheral abscess with reaction of the overlying pleura external drainage done earlier than heretofore generally practiced, and based on accurate localization of the lesion, would seem to be indicated

In abscesses which fail to respond to active medical therapy in two or three months, especially in children whose general condition is good such radical surgery as lobectomy deserves early serious consideration, in order to avoid progression to chronic pulmonary suppuration and gangrene

The prophylaxis of lung abscess includes careful operative technic caution in operating on patients with any predisposition to atelectasis, close observation of lung ventilation during and after operation, conservative surgery on the upper respiratory tract with the use, if possible, of local anesthesia, improved oral hygiene and adequate therapy of respiratory infection in the early stages

REPORT ON MEDICAL PROGRESS

THE LEUKEMIAS*

HENRY JACKSON, JR., M.D.†

BOSTON

LEUKEMIA may be defined as an acute or chronic systemic disease involving primarily the blood-forming organs, characterized by a widespread, disorderly and profitless proliferation of the leukocytes and their precursors, manifest by the presence, often in very large numbers, of immature or abnormal white cells in the peripheral blood stream, and leading, at least in the vast majority of cases, to death within a comparatively short time

CLASSIFICATION

From a clinical viewpoint, there is a rather sharp distinction between acute and chronic leukemia, and some authorities believe that there may be a fundamental difference in their essential nature and etiology. It is usual to classify the leukemias according to the particular type of white cell involved. We have, therefore, myelogenous, lymphatic and monocytic leukemia. The latter^{1, 2} is almost always acute, and in the opinion of some investigators constitutes the majority of the cases of acute leukemia in adults. In addition, there have been described eosinophilic³ and plasma-cell⁴ leukemia. For most practical purposes it is probably sufficient to disregard the latter two forms, which at best are extremely rare, and to group all types of acute leukemia together as one clinical entity. It is advantageous, however, to retain a sharp distinction between chronic lymphatic and chronic myelogenous leukemia.

GENERAL OBSERVATIONS

Fortunately, leukemia is a rare disease. It is difficult to estimate its frequency with any degree of accuracy. In 8693 autopsies at the Boston City Hospital from 1920 to 1939 the condition in one form or another was encountered 78 times. During the same period a clinical diagnosis was made 333 times among 324,785 admissions to the medical and surgical wards. These figures closely approximate those of Ordway and Gorham,⁵ who estimate that 1 case of leukemia occurs in every

1000 general hospital admissions. It must be remembered, however, that not a few patients with leukemia are nowadays referred by their physicians directly to hospitals whose staffs are particularly interested in the condition and which are especially equipped to treat the disease. Such cases are, therefore, not frequently seen on the wards of a general hospital.

All types of leukemia are much commoner in men than in women. This is especially true of chronic lymphatic leukemia.⁶

Acute leukemia is commonest in the early decades, a major peak being reached in the first five years of life, and a secondary though still significant rise occurring early in the second decade. While the disease may be seen at any time of life, it is distinctly rare after the age of fifty.

Chronic myelogenous leukemia is most commonly encountered between the ages of twenty and sixty, and reaches its greatest incidence between the ages of twenty-five and thirty-five, whereas chronic lymphatic leukemia is most often seen in persons between forty-five and sixty years of age. Any form of chronic leukemia is rare under the age of ten.

The etiology of leukemia is unknown, though it is probable that the chronic forms are closely related to the true neoplastic diseases, and some competent observers believe that the acute forms, while perhaps also of malignant nature, are more intimately related to infection.⁷ Furth and his associates,⁸ on the basis of extensive studies of experimental leukemia in mice, have concluded that all types of leukemia are true neoplastic diseases.

There are certain changes in the bodily economy common to all types of leukemia, and these should be referred to briefly. In all, the basal metabolic rate may be considerably increased⁹ thus giving rise to certain signs and symptoms such as tachycardia, increased sweating, loss of weight, nervousness and easy fatigability, all reminiscent of hyperthyroidism. The basal metabolic rate may thus be of some value in the differential diagnosis of leukemia and the leukemoid states, and may further be of value in determining the need for therapy and the results thereof. The nitrogen balance varies within wide limits, but

From the Thorndike Memorial Laboratory and the Second and Fourth Medical Services (Harvard) Boston City Hospital, the Department of Medicine, Harvard Medical School, and the Collis P. Huntington Memorial Hospital, Boston.

†Assistant professor of medicine, Harvard Medical School, associate physician, Thorndike Memorial Laboratory, Boston City Hospital, and Collis P. Huntington Memorial Hospital, Harvard University.

particularly in acute leukemia it is liable to be negative and the serum proteins tend to be low. These facts should be borne in mind when considering the therapy of the disease, the diet should at all times contain an adequate amount of protein for the individual needs, and it should be remembered that often large amounts of protein and nucleoprotein are lost to the body each day.

Anemia of the normocytic and normochromic type is an almost invariable accompaniment of the disease sooner or later. This anemia is chiefly a myelophthisic one, due to the overcrowding of the marrow by the exuberant growth of leukocytes, but in certain cases it may be greatly enhanced by hemorrhage, particularly into the gastrointestinal tract. The presence or absence of anemia is of great diagnostic value in the acute forms, and in both acute and chronic leukemia progressive anemia may bring about symptoms of major importance and call for specific and energetic therapy. The presence of severe anemia usually indicates an early fatal outcome, especially in the acute and the chronic lymphatic types.⁴

Any form of leukemia, but more especially the acute, may be accompanied by spontaneous hemorrhages of minor or major clinical importance. In the acute forms, this hemorrhagic state is dependent to a great extent on the frequent paucity of blood platelets, in the chronic leukemias the same may be true, but there is the added factor, not manifest in the peripheral blood stream, of direct damage to the finer blood vessels by the invading leukocytes.

It is of the utmost importance to recognize the fact that any organ or structure of the body may be involved by the leukemic process, for thus are the extremely protean signs and symptoms of the disease brought about. It is perhaps germane to the present purpose to draw attention to lesions of five systems in particular, for lack of recognition of the fact that these systems are frequently involved may lead to failure to recognize the fundamental systemic disorder, or failure to treat as leukemic manifestations symptoms or signs easily attributable to other causes.

In the mouth and pharynx, there may be ulcerations, necrosis, bleeding and even noma, especially in the acute forms of the disease. Monocytic leukemia in particular is associated with severe oral lesions.² It is not unusual to find in acute leukemia that the first symptom is unexpected bleeding following a minor operation such as a simple tooth extraction. More than one patient with leukemia has first consulted his dentist for a supposedly local sign or symptom, and I know of one oral surgeon who very wisely al-

ways does a complete blood examination in any puzzling or peculiar "mouth case." It should further be borne in mind that in elderly people a sore throat of unusually long duration or enlargement of the tonsils without obvious infection may be due to lymphatic leukemia.

The eye is involved sooner or later in over half the cases of leukemia,¹⁰ though obvious clinical manifestations may not be present. Retinitis, retinal hemorrhages, edema of the disks and marked engorgement of the vessels are the commonest changes noted. Diminution of visual acuity is not rare, and sudden blindness may be the first symptom noted. Exophthalmos, either unilateral or bilateral, may occur, especially in children.

The central nervous system is similarly often involved,¹¹ lesions of the cranial nerves, reflex changes and hemorrhages, large or small, being the most commonly seen. In rare cases, meningitis is simulated and in the sterile spinal fluid are seen the immature cells characteristic of the individual type of leukemia at hand.

In the skin a bewildering variety of lesions occurs.¹² Indeed in certain cases the chief, if not the only clinical manifestation is a dermatologic one. There may be single or multiple nodules, often of a quite nonspecific character. Or there may be, particularly in chronic lymphatic leukemia, a diffuse reddening and scaling of the skin accompanied by intense itching. As in the non-leukemic lymphomas, herpes zoster is not uncommon, and in rare cases it may be of universal distribution.

Changes in the bones or symptoms related thereto are common and important, particularly in the acute leukemia of children, in whom rheumatic fever may be closely simulated.^{13, 14} The fact that children with leukemia often present a peripheral blood picture which is atypical makes this fact particularly significant, for the joint symptoms may so dominate the clinical picture that the true diagnosis is completely overlooked.¹⁵ Periosteal infiltrations and a moth-eaten mottling of the ends of the long bones as shown in the roentgenogram are particularly suggestive of a leukemic process.

It is thus obvious that the clinical manifestations of leukemia are most varied and that the presenting signs and symptoms may not necessarily suggest the widespread nature of this uniformly fatal disease, which may at first manifest itself as a comparatively isolated lesion of a system which is only remotely connected with the blood-forming organs, and which not infrequently falls within the province of the specialist rather than that of the general internist.

As has been said above, for most practical pur-

poses all types of acute leukemia, whether lymphocytic, monocytic or myelogenous may be regarded as one and the same disease. This is so because the prognosis and treatment in all are essentially the same. For those particularly interested in the more exact and definitive classification of the acute leukemias, we refer to the studies of Forkner.

ACUTE LEUKEMIA

The onset of acute leukemia is usually insidious, more rarely abrupt. It should be constantly borne in mind that the disease is essentially one of infancy and childhood, though no age is spared. Often an ill defined and gradually increasing weakness or an unexplained torpor and lassitude constitute the presenting symptoms. Equally common, and equally deceiving to the unwary, are symptoms of sore throat, ulcerations of the buccal mucosa or hemorrhages following some minor surgical procedure. Only too often, the localized nature of the symptoms overshadows the systemic nature of the disease. Peirce¹⁰ has drawn attention to the fact that in many cases the first symptoms seem to be related to upper respiratory infection from which the child does not recover as it would seem he should. A gradually increasing pallor may be the sole sign apparent. Nausea, vomiting, abdominal pain, melena and anorexia are not infrequent. Occasionally these may be of such character as to suggest an acute abdominal emergency, and patients have been operated on for supposed appendicitis or acute intestinal obstruction.¹¹ Fever, often of a septic type, is usually present, and may be seen even when the patient appears to be in good general condition.

Early in the course of acute leukemia the physical examination may be essentially normal. Sooner or later, however, there is usually generalized enlargement of the lymph nodes and the spleen is commonly palpable on deep inspiration. Hemorrhages into the skin, mucous membranes and eye grounds are common. The frequent oral lesions have already been discussed. Occasionally—and these cases may be most deceptive—acute leukemia in children masquerades as rheumatic fever.¹² It is most important to remember that under a variety of signs and symptoms—many of them apparently of minor importance—may lurk one of the most dreaded of all children's diseases.

The peripheral blood in the majority of cases shows a characteristic picture. The white-cell count may be normal, moderately elevated or markedly depressed. Leukopenia is particularly prone to be found in the early stages of the disease. Only rarely does one encounter the great increase in white-cell count so frequently seen in the chronic

leukemias, and it cannot be emphasized too often that the total white-cell count per se has little or nothing to do with the diagnosis.

In the classic case, there is a preponderance of very immature white cells of one or another series. Often stem cells, characterized by their deep blue cytoplasm and their prominent nucleoli within the nucleus, predominate in the blood smear. If 90 per cent of the white cells—no matter what the total count and no matter what the symptoms—are true stem cells the diagnosis is almost certainly acute leukemia. But an occasional stem cell may be found, especially in children, in a large variety of conditions, and one must always be cautious before making a final diagnosis. Relatively mature white cells of any series may compose the majority of the white cells in the blood smear, and rarely there are but few very young white cells present. Under the latter circumstances it is most difficult to diagnose acute leukemia with any assurance. Occasionally one finds the so-called hematologic hiatus, in which there are present in considerable numbers both extremely immature and quite mature white blood cells. No intermediate forms are present. Under these circumstances a diagnosis of acute leukemia is almost certain.

The platelets in acute leukemia are almost invariably greatly reduced in number, and this fact is of the highest importance in differentiating this disease and certain cases of overwhelming infection in which as a rule the platelets are increased in number, often markedly so.

Sooner or later in acute leukemia a moderate or severe anemia develops. It must be remembered, however, that the life of the red cell in the peripheral blood is such that anemia arising primarily from bone-marrow failure does not take place for a matter of weeks, so that the absence of anemia in the presence of other unequivocal signs and symptoms of leukemia should not be construed as evidence against such a diagnosis if the case be seen early.

Thus progressive anemia, a preponderance of very immature white cells in the blood smear and thrombocytopenia usually indicate the presence of acute leukemia. If there be in addition splenomegaly and slight generalized lymphadenopathy, the diagnosis becomes practically certain. It is important to remember, however, how protean may be the clinical manifestations of the disease and how variable the blood picture.

Acute leukemia must be differentiated chiefly from infectious mononucleosis, aplastic anemia, agranulocytic angina and overwhelming sepsis.

Infectious mononucleosis may usually be distinguished by the presence of the characteristic white

cells of this disease,^{17 18} by the absence of anemia and thrombocytopenia and by the presence of a positive sheep-cell agglutination test.¹⁷ This test is never positive in leukemia, and if positive in dilutions of 1/64 or greater is clear evidence that one is dealing with infectious mononucleosis, unless there has been a recent administration of horse serum.

In aplastic anemia there are few if any really immature white blood cells in the peripheral smear and classically all three essential formed elements of the blood are concomitantly diminished. The basal metabolic rate is not increased, and there is rarely splenomegaly and never generalized lymphadenopathy of any moment. Yet in certain cases it may be impossible without bone marrow biopsy to be confident of the diagnosis.

Cases of acute leukemia have often been erroneously diagnosed as agranulocytic angina.¹⁹ In view of the different prognosis and treatment of the two conditions, it is of the utmost importance to differentiate them clearly. In general it may be said that in agranulocytic angina anemia and thrombocytopenia are absent, that extreme leukopenia is the rule and that one rarely sees immature white blood cells in any number during the acute stage of the disease. During recovery however the white-cell count may occasionally rise to 20,000 or even 100,000 and there may be many myelocytes and even younger white cells in the blood. Under these circumstances it may be difficult to say whether one is dealing with a marrow overactive following a period of pathologic inactivity or with leukemia. Agranulocytic angina is very rare in children but to make matters more difficult what appears to be the true disease has been followed after weeks or months of remission by true acute leukemia. The majority of these cases have been those of children or very young adults, so that one should always be most cautious in regard to prognosis of the leukopenic state in this age group.

Overwhelming sepsis may manifest itself by anemia and by the presence in the blood of extremely immature white cells often in considerable number. Usually however the platelets are increased rather than decreased in number and in the majority of cases, the infection has obviously preceded the development of the abnormal blood picture so that the differential diagnosis is clear. But when one remembers that sepsis is a common complication of acute leukemia one realizes the difficulty of making an accurate diagnosis in any given case. When in doubt it is probably wise to treat the case as one of infection and give a guarded prognosis.

The course of acute leukemia is almost invariably progressive onward to death within a few weeks or months. Very rarely there may be remissions of considerable duration, during which the patient returns to apparent health and the blood picture is normal.⁶ The physician must be careful not to allow such temporary improvement to lull him into a false sense of security.

There is no form of treatment known that affects the course of acute leukemia. X-ray therapy is seldom of even temporary advantage, and it may cause severe reactions. If the diagnosis of acute leukemia is clear radiation is probably contraindicated. If there is an anemia causing untoward symptoms, transfusions of blood may be given but severe reactions are liable to take place even with correctly matched bloods. One of the most difficult tasks which confront the physician is that of withholding any treatment other than symptomatic in these cases. Yet such is usually the wisest course and the best that one may hope for is that the end will come quickly or that one's diagnosis is incorrect.

CHRONIC MYELOGENOUS LEUKEMIA

The onset of this disease is usually insidious, and the condition has most often been in progress for many months by the time the patient seeks medical advice. The commonest symptoms are loss of weight and strength, increased sweating, weakness and distention of the abdomen. Often there is generalized abdominal discomfort especially after meals owing to the presence of a greatly enlarged spleen which encroaches on and interferes with the gastrointestinal tract. More rarely there may be acute pain in the splenic region attendant upon the very common splenic infarcts. Pallor, dyspnea, nausea and anorexia are common. Occasionally there may be a marked hemorrhagic tendency. Eye symptoms are not unusual and may be due to retinal exudate, hemorrhages or edema of the disks.

When the patient is first seen the spleen is usually enlarged, often greatly so, but early in the disease, splenomegaly may not be a prominent feature and its absence does not exclude a diagnosis of leukemia. Moderate hepatomegaly is usually present. Generalized lymphadenopathy is rare but occasionally enlarged lymph nodes are found in the neck, axilla and elsewhere.

The total white count is classically elevated—often to a very great degree. White counts of 200,000 to 500,000 are not unusual and counts well over a million have been reported. It must however be constantly borne in mind that the total white count per se is not the most important fac-

tor in the diagnosis. One may find white counts of 150,000 and over in patients who do not have leukemia and patients with leukemia may show a marked lowering of the total white count. The important feature, in so far as the blood is concerned, is the increased percentage of very immature cells. In the average case, myelocytes in various stages of development comprise the majority of the cells, varying from 10 to 80 per cent. Stem cells are seen in the more rapidly advancing types, but very rarely to the degree seen in acute leukemia. It is important to bear in mind that marked fluctuations in the total white-blood-cell count and in the differential may occur without any treatment whatever and that these variations are of little or no prognostic value.

Sooner or later a normocytic, normochromic anemia develops and the red cells often show a polychromatophilia and a considerable number of nucleated red cells. The platelets may be normal, increased or decreased in number. A marked decrease is of grave prognostic import.

The usual case with splenomegaly, greatly increased white-cell count and immature granulocytes can be diagnosed with some assurance, but it is important to recognize that a wide variety of conditions may give rise to a leukemoid blood picture.¹⁵⁻²¹ Space does not permit an analysis of the differential points involved, but it should be mentioned that blood pictures simulating myelogenous leukemia may be seen in sepsis, metastatic carcinoma, miliary tuberculosis, sulfanilamide poisoning, polycythemia vera and especially in agnogenic myeloid metaplasia.²² In this last condition, which may very closely simulate myelogenous leukemia, particularly in the aleukemic phase, x-ray treatment should be given with the greatest caution if at all, for the chief seat of blood formation in these cases is the spleen. It is obvious that if by radiation one destroys even in part the sole or major source of blood formation, one may do more harm than good.²²⁻²³

The disease is usually steadily progressive and leads to death in two to four years. Some 10 per cent of patients survive ten years or more from onset. In the majority of cases the course of the condition is such that the experienced physician can foretell with some accuracy when a fatal termination is near, but it should be pointed out that sudden and unexpected death (usually from cerebral or gastrointestinal hemorrhage) occasionally occurs, and the family should be apprised of this fact.¹⁵

To date, the most effective treatment is irradiation of the spleen. It is best to leave the exact amount of irradiation given to the radiologist in

charge, but certain generalities may properly be pointed out. As a rule, one gives to the spleen approximately 600 r at 250 kilovolts in divided doses over a period of a week to ten days, watching the white-cell and differential counts carefully during the treatment. The white-cell count should not be allowed to fall below 15,000 or 20,000 (when it has previously been greatly elevated). If the initial counts are already relatively low, x-ray treatment should be undertaken with caution. The beneficial results in so far as the patient's general sense of well-being is concerned often do not take place for a matter of several weeks, and this fact should be drawn to the patient's attention before therapy is instituted. If the initial red-cell count is below 3,500,000, one or more blood transfusions are indicated before irradiation therapy is undertaken. If the platelets are few, x-ray therapy should be undertaken with caution. It should be pointed out, however, that appropriate radiation therapy in cases of myelogenous leukemia not infrequently results in an increase of platelets when these elements have previously been few in number.

Further treatment, after the first course, may be withheld until such time as the patient's symptoms appear to call for alleviation. It is well to remember that it is problematical whether life is prolonged by irradiation, and that our efforts should be aimed chiefly at the alleviation of symptoms rather than the mere reduction in the total white-cell count.

If x-ray therapy is not available, — and at present it is available only in the large centers, — one may advantageously use Fowler's solution by mouth. For the details of such treatment, the reader is referred to the article by Forkner.² In general, it may be said that from 5 to 40 minims of Fowler's solution are given three times a day until the desired lowering of the white-cell count has taken place, and the patient is then continued, with rest periods, on a small maintenance dose. It is important to recognize, however, that treatment by arsenic must be carefully suited to the individual case, and in all instances the dosage must be very gradually stepped up from the minimum to the optimum. Unfortunately, while it is true that marked improvement in the blood picture can usually be brought about by this form of treatment, the fact remains that toxic manifestations such as anorexia, skin lesions, diarrhea and peripheral neuritis are not uncommon, and they may render the patient even more uncomfortable and ill than does the fundamental disease, so that x-ray therapy remains the treatment of choice.

In our enthusiasm for x ray therapy and our satisfaction with the results obtained, we should not lose sight of the advisability and indeed the necessity of general supportive measures. Adequate diet, plentiful in vitamins and proteins, should be maintained. Proper rest periods during the day may enable a patient to carry on his activities with reasonable success. Iron in the form of ferrous sulfate is frequently helpful. Transfusions of blood—often repeated many times—are of great advantage if there be a marked anemia.

CHRONIC LYMPHATIC LEUKEMIA

There is a close relation between lymphatic leukemia and lymphosarcoma. The latter condition may be widespread and reach massive proportions without there being any manifestations of the condition in the peripheral blood, but not infrequently a patient with an isolated lymphosarcoma will, with the passage of time, develop the peripheral blood picture of classic lymphatic leukemia, and conversely there may arise in patients with lymphatic leukemia large tumor masses in the mediastinum or elsewhere. For most practical purposes these two conditions may be regarded as identical.

Chronic lymphatic leukemia occurs in an older age group than does chronic myelogenous leukemia and is less amenable to treatment but is more likely to run a long and relatively benign course.

Not infrequently the disease is for a long time symptomless. Each year in any large general hospital cases with the disease but with no symptoms attributable to it, are discovered on the medical or surgical wards solely through routine blood examinations. The commonest symptoms are weakness, pallor, general malaise, vague gastrointestinal symptoms, general enlargement of lymph nodes and a hemorrhagic tendency. In certain cases a diffuse reddening and itching of the skin is the presenting and indeed the only symptom. Both melena and hematuria are seen with sufficient frequency to merit particular attention.

On physical examination one may find nothing of note. More usually, however, there is a widespread lymphadenopathy, the lymph nodes themselves being of a fairly uniform size and distribution and of the consistence of soft rubber. The spleen is usually enlarged, though only rarely does it reach the massive size attained in chronic myelogenous leukemia.

The white count may be normal, subnormal or—most commonly—greatly elevated. White cell counts of over 500,000 are not unusual. The differential count shows an overwhelming pre-

ponderance of lymphocytes, the majority of which appear normal. In the more rapidly advancing cases it is usual to find a certain percentage of young lymphocytes, though their presence even in considerable quantities does not invariably indicate an early fatal outcome, as is witnessed by the fact that one patient—a sixty-five-year-old man—has had some 20 per cent of lymphoblasts in the peripheral blood stream for a period of six years but is still able to carry on an active and strenuous career. Anemia is an almost invariable accompaniment sooner or later. The platelets may be increased in number, but more commonly they are sharply decreased, and their paucity in this disease does not carry the same unfavorable prognosis that the similar finding in chronic myelogenous leukemia does.

In the typical case the diagnosis can hardly be missed, but when there is an associated leukopenia it may be almost impossible to make, and on occasion the disease must be distinguished from pertussis, infectious mononucleosis, aplastic anemia and rarely atypical tuberculosis.

On the average, patients with chronic lymphatic leukemia survive only three or four years from onset of the disease, but fully 10 per cent live ten years or more, and rarely the patient may survive an even longer time, and even then succumb to some other quite unrelated condition.¹⁴ This fact should be borne in mind, particularly in elderly people with few or no symptoms referable to the leukemic picture.

As with chronic myelogenous leukemia, irradiation of the spleen or chest, preceded by blood transfusions if there is a co-existing anemia of moment, is the treatment of choice. It is very questionable, however, whether there is any advantage in treating those patients who are symptomless. The details of the x ray therapy should be left to the radiologist in charge, but the same general principles hold as with chronic myelogenous leukemia.

In certain cases, Navitol in large doses—50 or 75 drops a day—seems to be advantageous, particularly in alleviating itching in those patients who have generalized skin lesions. If tumor masses of lymphosarcoma arise and cause symptoms, irradiation should be given directly to them.

CASE RECORDS OF THE MASSACHUSETTS GENERAL HOSPITAL

ANTHEMORTEM AND POSTMORTEM RECORDS AS USED
IN WEEKLY CLINICOPATHOLOGICAL EXERCISES

FOUNDED BY RICHARD C. CABOT

TRACY B. MALLORY, M.D., *Editor*

CASE 26011

PRESENTATION OF CASE

A seventy four year-old Swedish widow was admitted to the hospital complaining of pain in the lateral side of the right knee of three and a half to four months duration.

The patient was well until four months before admission when all but four of her teeth were removed because of "pyorrhea." The extractions were performed without known complication. About three and a half months before entry, without known trauma, she first felt a slight transient stabbing non-radiating non-throbbing pain in the lateral side of the right knee. The pain increased rapidly in severity and in duration so that about two months before admission she was forced to stop her daily housework. She went to bed for two weeks and applied liniments locally but without improvement. She was able to work again for a few weeks, but was forced to stop when the pain on motion of the joint became so severe that at times she felt faint. However, there was no discomfort when the leg was at rest. The knee had been slightly swollen since the onset of her illness, but it increased rapidly in size during the three weeks before admission. She had been unable to walk for two weeks because of pain. She lost about 5 pounds in weight (normal weight 160 pounds) during the present illness.

Physical examination revealed a fairly well developed and nourished woman in no apparent acute distress. The examination was negative except for that of the right leg which showed a painful, swollen, questionably fluctuant hot area located above and lateral to the knee. The overlying tissues were tense and relatively immobile.

The temperature was 99°F., the pulse 110 and the respirations 20.

Examination of the blood showed a red-cell count of 4,200,000 with 70 per cent hemoglobin (Tallqvist) and a white-cell count of 15,800 with 83 per cent polymorphonuclears. The corrected sedimentation rate was 1.2 mm a minute. The urine was negative, there was no Bence Jones protein. The blood Hinton test was negative. The serum calcium was 10.2 mg per 100 cc., the

phosphorus 4.3 mg, and the serum phosphatase 57 units. X-ray examination showed a localized area of bone destruction in the lower end of the right femur, it began at the anterior joint margin and extended upward 4.5 cm. The lesion was about 3 cm in depth and ulcerated, with a 3-cm soft-tissue mass. There was slight periosteal proliferation more marked on the medial aspect of the femur slightly away from the area of destruction, this reaction simulated "collar formation." There was also some new-bone formation at the margins of the lesion, seen best in the antero-posterior view. The soft tissues were only slightly thickened. There was no fluid in the joint. The patella was elevated and slightly below its normal position. The left knee and other bones were normal. The chest was negative. An intravenous pyelogram was negative. A barium enema was negative.

On the fifteenth hospital day an operation was performed.

DIFFERENTIAL DIAGNOSIS

DR THOMAS J. ANGLEM: The important fact in this case is that we have a destructive lesion in the lower end of the femur in a woman aged seventy four who gave a story of pain referred to the lateral aspect of the knee for three and a half to four months, gradually increasing in severity and associated with progressive swelling referred to that part. I think we should save considerable speculation and exploration of blind alleys by viewing the x-ray films.

DR AUBREY O. HAMPTON: I cannot add anything to the description in the record. I can point out the things that were described. The lesion is here, it is almost a purely destructive process, which extends down to and underneath the cartilage of the knee. It does not destroy the cartilage but is exactly against it and forms an area of destruction somewhat similar to that of a giant cell tumor. The remainder of the findings are not the least bit similar to those of a giant-cell tumor. The "collar formation" here is quite definite. We thought we could rule out an infectious process because there was no fluid in the joint.

DR ANGLEM: The first problem is, as Dr Hampton has already said, to rule out an infectious process. I think we might well attack the differential diagnosis by eliminating one possibility after another. The first paragraph provides material for a tempting hypothesis. The patient was said to have had extraction of all but four of her teeth for pyorrhea, and it is not unreasonable to assume that she may have had apical dental infection. The trauma incidental to dental ex-

mine the exact nature of the tumor. The entire knee joint was full of this material. We were much impressed with the lining of the cavity, it was not the smooth lining that you see in benign giant-cell tumor, and the depth of the cavity was much greater than that indicated by the x-ray film. For that reason we did not accept the diagnosis of giant-cell tumor and continued with the amputation.

CASE 26012

PRESENTATION OF CASE

A twenty-five-year-old Negro, born on Cape Verde Islands, was admitted to the hospital complaining of pain in the left upper arm.

Six years before admission the patient noticed a moderately severe, non-radiating, aching pain in the middle of his left upper arm. The pain responded favorably to "liniment" and massage, and he was asymptomatic after two or three days. Since then he had suffered similar yearly recurrences, without swelling, local heat, radiation of pain, chills or fever. Between attacks he felt well and was able to work as a picker in a Cape Cod cranberry bog. Six months before entry, however, the pain became much more severe and involved the left elbow, and he was unable to use the arm for two to three weeks. Since then he had experienced almost monthly attacks of pain in either the elbow or middle arm, and for two months before entry, the discomfort had been constant. Five days before admission the left arm and elbow became swollen, hot and very painful. He was unable to move the elbow joint and held it in a semiflexed position in a sling. There were no other symptoms.

Physical examination revealed a well-developed and well-nourished man in no acute distress. The examination was entirely negative except for the left arm. The elbow was held in semiflexion, the upper arm was hot, puffy, edematous, but non-fluctuant. There were no palpable axillary lymph nodes. The arm was protected by the patient and held in semiflexion. The blood pressure was 130 systolic, 70 diastolic.

The temperature was 98°F, the pulse 80, and the respirations 20.

Examination of the urine was negative. The blood showed a red-cell count of 3,600,000 with 80 per cent hemoglobin (Sahli), and a white-cell count of 12,200 with 81 per cent polymorphonuclears, the blood smear was negative. The tuberculin test, using 0.1 cc of a 1:10,000 dilution, was negative. Two blood Hinton tests were positive, the Wassermann test negative. The blood nonprotein nitrogen and serum protein determina-

tions were normal. The spinal-fluid Wassermann and gold-sol tests were negative, the spinal-fluid protein was 14 mg per 100 cc.

Roentgenograms of the left humerus showed a loculated cavity involving the medulla of the mid-third of the shaft of the humerus about 13 cm in length. The cavity was fairly well defined in its lower end but poorly defined in its upper end where there was apparently some destruction in the adjacent bone. The cortex was destroyed

FIGURE 1 *Left Humerus the Day of Operation*

in at least three places and was thinned in others. There was marked rough periosteal new-bone formation over the lesion, as well as over the area of destruction at its upper margin. There was soft-tissue swelling about the lesion, and this appeared to be due to edema. An area of increased bone density lay close to the lower edge of the lesion. There was no evidence of pulmonary lesions. Films of the pelvis, bones of the hands, femora, tibia, knee joints and skull showed no abnormalities. Intravenous pyelograms showed several areas of calcification overlying the upper pole of the left kidney, and apparently outside it.

The patient ran an irregular, spiking type of temperature, ranging from 98.6 to 103°F. An x-ray film (Fig 1) taken about two weeks later, on the day of operation, showed essentially the same changes.

DIFFERENTIAL DIAGNOSIS

DR. FULLER ALBRIGHT I do not know much about bone disease of this type. May I see the x-ray films?

DR. AUBREY O HAMPTON I know the answer so I prefer that you ask questions.

DR. ALBRIGHT The periosteal proliferation suggests syphilis. We notice that the epiphysis of the bone is not involved. In other words, it is a midshaft process. I do not believe the calcification over the kidney can possibly be in the adrenal gland. Is that correct?

DR. HAMPTON Yes, it looks like a tuberculous node.

DR. ALBRIGHT I have no other questions. Have you any other comment not brought out by the description?

DR. HAMPTON No.

DR. ALBRIGHT What does one consider? The first possibility is tumor. The facts that there was no soft-tissue mass and that the lesion had lasted six years are against tumor, especially a Ewing tumor. There is no evidence of another type of tumor, hence tumor is unlikely. Secondly, one should think of infection. In the beginning the absence of fever was against infection, however at the time of admission the fever and white count were strongly in its favor. The various types to consider are tuberculosis, syphilis and chronic osteomyelitis. Tuberculosis does not usually start at the midshaft. The pain is somewhat against syphilis, but the positive Hinton test and the periosteal proliferation are in its favor. It is most unusual not to have a positive Wassermann test in active syphilis. I do not believe he had bone syphilis, but it remains a distinct possibility. The symptoms of chronic pyogenic osteomyelitis can be very obscure and these areas of increased density around the bone certainly look like those of osteomyelitis. The facts are consistent with such a diagnosis, and I do not believe it can be ruled out.

DR. HAMPTON What do you think of the sharp cystic appearance of the areas of rarefaction?

DR. ALBRIGHT It fades out up here, but, as you say, is sharp on this side. There is no sequestrum which if present would favor osteomyelitis, but I do not believe that sequestration necessarily occurs in osteomyelitis. This diagnosis cannot be ruled out and is my best bet.

The third possibility is bone cyst. However, the general appearance of the lesion is not like that of a bone cyst, and I do not believe it is going to turn out to be that. Why I say this, I do not

know, other than because it does not look like it to me.

DR. HAMPTON How about the periosteitis?

DR. ALBRIGHT Think you, the presence of periosteitis is strong evidence against bone cyst.

Somebody probably wants me to talk about the syndrome characterized by osteitis fibrosa disseminata, areas of pigmentation and precocious puberty in females.* He was brown all over so he could not have brown spots. It is not that syndrome anyway. When that condition involves the shaft of a bone, it goes to the metaphysis and is not confined to the middle of the bone. Some one might consider xanthoma. I have seen the disease in a case associated with periosteal proliferation, but in the absence of other bone involvement it is most unlikely.

Because of the fever and elevated white count I am going to stick to the diagnosis of chronic pyogenic osteomyelitis. My second choice is bone cyst.

DR. TRACY B MALLORY Dr. Albright's diagnosis agrees with that of the local practitioner who sent the patient in but its correctness was questioned for a long period of time in the hospital and many questions were raised. Have you any thing to add, Dr. Hampton?

DR. HAMPTON I am startled with the simplicity of the case. We had several conferences over this patient, one with the Tumor Clinic. We started out with the impression that by x-ray the lesion in the bone was more like that of syphilis than of any other disease. His clinical manifestations, however, were not typical, and then we thought perhaps it was tuberculosis of the shaft which does occur in Negroes, Chinese and certain Scotchmen. However, tuberculosis usually involves the ends of the bone instead of the midshaft. We ended up by believing the lesion was due to an infection. One member thought that a Ewing tumor was a definite possibility. It was not so simple to us as it was to Dr. Albright.

DR. GRANTLEY W. TAYLOR We had the problem of disposing of this patient and did not know in which of several directions to send him. He was on the osteomyelitis service, but Dr. Daland had the bone-tumor assignment, and the syphilologists began to "lick their chops" as soon as the positive blood test was returned. It seemed simplest to let the syphilologists try intensive antisyphilitic treatment. So this was carried out for a period of two weeks, without any striking improvement. Against the diagnosis of syphilis was the complete

seminata and
precocious
puberty.

freedom from other evidence of the disease. The arm symptoms had started six years before entry, at the age of nineteen, and hence if the process were due to primary syphilis, the disease must have been acquired at an earlier time, however, there was no history, and no other stigmas. We wondered if this might have been a false-positive Hinton test, and a syphilologist raised the question as to whether the febrile reaction might have accounted for the positive test. It was a very interesting possibility which I had not seen brought out before.

We tried aspiration with a needle and got nothing. Because of that we finally explored him. We got a copious immediate discharge of pus, and when a probe was introduced the length of the cavity, more pus was evacuated. Cultures showed *Staphylococcus aureus*. He went ahead to a very rapid, serene convalescence. He was discharged after two weeks, with no symptoms—a most bizarre convalescence for a case of osteomyelitis. Tissue was given to the Pathological Department, and I believe Dr. Mallory will tell us that it showed a distinctly benign sort of process for osteomyelitis.

DR. HAMPTON: What were the gross findings in the shaft?

DR. TAYLOR: There was a thickened, edematous, red, porky periosteum, with practically no cortex. We dropped immediately into an abscess cavity, and inside of that was the usual chronic inflammatory, granulation tissue.

CLINICAL DIAGNOSIS

Tertiary lues?
Osteomyelitis?

DR. ALBRIGHT'S DIAGNOSIS

Chronic pyogenic osteomyelitis

ANATOMICAL DIAGNOSIS

Chronic osteomyelitis of humerus, *Staphylococcus aureus*

PATHOLOGICAL DISCUSSION

DR. MALLORY: The clinical course, I think, is the most important proof that the *Staphylococcus aureus* was at least the immediate cause of this patient's difficulties, because as soon as the abscess was drained, as Dr. Taylor has pointed out, he had an immediate symptomatic improvement, which continued on to apparently complete cure. The material excised from the margins of the cavity appears to consist of granulation tissue, very heavily infiltrated with lymphocytes and plasma cells, there are quite a lot of lipid-filled cells, but not enough to make one think seriously of xanthoma. I think there is a possibility that something existed before the abscess developed, but I do not know any way of proving it.

DR. HAMPTON: This is not the first time our department has had considerable difficulty with a staphylococcal abscess. We have quite a series of them. They mimic bone tumors and practically everything else, especially when the lesion has been present a long time.

DR. ERNEST M. DALAND: You cannot find any evidence of syphilis?

DR. MALLORY: No. I should think if syphilis entered the case at all it was congenital rather than acquired.

ANTI VIVISECTION

In an attractive illustrated folder the people of New England are being asked by the New England Anti Vivisection Society to support the cause of anti vivisection as being the cause of all right thinking individuals. Since most of us secretly pride ourselves on our right thinking we believe that this appeal is addressed to us.

We are told that thousands of people are learning for the first time that vivisection really means animal experimentation, that the path of cruelty does not lead to man's birthright, nor will man find relief from pain in the "broken and tortured bodies of those weaker than themselves and that among the victims of vivisection are not only animals but also "the less fortunate among human beings. A police dog looks out from the page with eyes of canine honesty. A kitten appears to typify helplessness. The human victims do not appear

This folder purports to be a sincere appeal to the people of New England to correct an evil by the abolishment of animal experimentation, a procedure which is motivated by cruelty and exists for the purpose of causing suffering to animals and unfortunate human beings. Need any intelligent person be disturbed by such an appeal?

The fight against cruelty in all its forms has always appealed and will always appeal to the best in human nature—of which, be it said in passing the medical profession has its full share. Experimentation on living creatures is essential to man's knowledge of disease on which in turn is based a large amount of what progress has been made against suffering and pain not only in human beings but also in animals. Should the misguided appeal of the New England Anti Vivisection Society fail to achieve the universal support of the people to whom it is addressed, such failure cannot fairly be credited to any lack of right thinking in New England.

SOURCES OF COMMON MEDICAL EPONYMS

THE most graphic and essentially the best description of a clinical syndrome or a medical procedure is commonly that given by its discoverer or originator in the first flush of his enthusiasm. He may not have known so much about the matter as hundreds of his successors, but what he said was the kernel about which subsequent knowledge grew. To give him the tribute of an eponym seems quite fitting and proper, and not unscientific, and hundreds of names of physicians and scientists are associated with various diseases, syndromes, signs, tests, anatomic parts, pathologic lesions and so forth. Such terms as Bright's disease, Horner's syndrome, Hegar's sign, Barany's test, McBurney's point and Brodie's abscess are constantly used by the medical profession, but few physicians have read the original contributions by Bright, Horner, Hegar, Barany, McBurney and Brodie in regard to these matters.

Some time ago, Dr. Robert W. Buck of Boston, submitted to the *Journal* a series of several hundred sources of common medical eponyms.

which he had collected over a period of years, and beginning with this issue, one will be published weekly. While the list selected by the editorial staff is purely arbitrary and makes no pretense of being encyclopedic, it is believed that the individual items are of sufficient general interest to constitute a valuable addition to the *Journal*.

MEDICAL EPONYM

ADAMS-STOKES DISEASE

Robert Adams (1791-1875), one of the surgeons to Jervis Street Infirmary, Dublin, describes "Cases of Diseases of the Heart, Accompanied with Pathological Observations" in the *Dublin Hospital Reports* (4 353-453, 1827). On page 391 appears the following:

February 20, 1822, I was called to visit a gentleman in my neighbourhood, aged 50 years, who had suddenly fallen down, as reported to me, in an apoplectic fit. I found him in a state of complete insensibility, his face (naturally pale and sickly) was now red and bloated, his breathing stertorous, with a slow pulse.

In the last year he had two apoplectic attacks, exactly resembling that which I had just witnessed from these he recovered without any paralysis of the muscles.

An officer in the revenue, aged 68 years, of a full habit of body, had for a long time been incapable of any exertion, as he was subject to oppression of his breathing and continued cough. In May 1819

I saw this gentleman. He was just then recovering from the effects of an apoplectic attack, which had suddenly seized him three days before. What most attracted my attention was the irregularity of his breathing, and remarkable slowness of the pulse, which generally ranged at the rate of 30 in a minute.

[During seven years he had been seen] in not less than twenty apoplectic attacks. He would then fall down in a state of complete insensibility. His pulse would become even slower than usual. He recovered from these attacks without any paralysis.

In both these cases apoplexy must be considered less a disease in itself than symptomatic of one, the organic seat of which was in the heart.

William Stokes (1804-1878) in his article "Observations on Some Cases of Permanently Slow Pulse," which appeared in the *Dublin Quarterly Journal of Medical Science* (2 73-85, 1846), refers to these case histories as follows:

In the fourth volume of the *Dublin Hospital Reports*, Mr Adams has recorded a case of permanently slow pulse, in which the patient suffered from repeated cerebral attacks of an apoplectic nature, though not followed by paralysis. The attention of subsequent writers on diseases of the heart has not been sufficiently directed to this case, which is an example of a very curious and, as there is reason to believe, special combination of symptoms.

PUERPERAL SEPSIS FOLLOWING DELIVERY

Mrs M. F., a thirty-year-old para IV, was delivered normally at home on July 19, 1926. There had been some difficulty in extracting the placenta. Following delivery the patient was weak and apathetic. On July 20 the patient complained of a sharp frontal headache and a pain in the back of her neck, which was worse on motion. She was therefore admitted to the hospital.

The family history was not recorded. The patient's past history was not remarkable. The three previous deliveries had been normal, with uneventful puerperiums.

Examination on entry revealed the temperature 102.4°, the pulse 140, and the respirations 24. The patient was conscious, rational and co-operative. The heart was not enlarged, there were no murmurs. The lungs were clear and resonant, there were no rales. The uterus was at the umbilicus, there was no tenderness, spasm or masses in the abdomen. The extremities were normal. The blood showed a white-cell count of 16,400, and the urine contained many pus cells.

She was given ice to the fundus, rectal fluids, urinary antiseptics, bladder irrigations and ergot. Improvement was gradual. For several days the temperature varied between 100 and 103°F, reaching a normal level on July 31. The white-cell count rose to 19,600 on July 26. The patient was discharged on August 8, completely recovered.

Comment. This is a typical case of uterine infection developing within thirty-six hours of delivery. The history states that some difficulty had been encountered in extracting the placenta. One does not know whether the placenta was extracted manually. If so, the infection was probably due to direct contamination. The patient's condition as described by the attending physician soon after delivery leads one to infer that hemorrhage was a complication. It is often true that patients whose temperatures rise within thirty-six hours are much sicker than those whose temperatures do not rise until after three days. No blood culture was taken. It is mentioned in the record that the patient was given ergot, it is not mentioned when the ergot

*A series of selected case histories by members of the section will be published weekly. Comments and questions by subscribers are solicited and will be discussed by members of the section.

was discontinued. It must always be borne in mind that continued use of ergot is dangerous and that its value after a few days is probably negligible.

MISCELLANY

RÉSUMÉ OF COMMUNICABLE DISEASES IN MASSACHUSETTS FOR NOVEMBER, 1939

| DISEASES | NOVEMBER 1939 | NOVEMBER 1938 | FIVE YEAR AVERAGE |
|---------------------------|------------------|------------------|----------------------|
| Anterior poliomyelitis | 7 | 0 | 14 |
| Chickenpox | 950 | 812 | 984 |
| Diphtheria | 28 | 21 | 28 |
| Dog bite | 533 | 656 | 605 |
| Dysentery bacillary | 36 | 9 | 13 |
| German measles | 135 | 30 | 62 |
| Gonorrhea | 426 | 421 | 514 |
| Lobar pneumonia | 269 | 233 | 260 |
| Measles | 857 | 597 | 384 |

| Undulant fever | 5 | 5 | 3 |
| Whooping cough | 508 | 557 | 607 |

Based on figures for preceding five years.

RARE DISEASES

Anterior poliomyelitis was reported from Adams, 1; Croton, 1; Haverhill, 1; Worcester 4 total 7.
Anthrax was reported from Peabody 1 total 1.
Diphtheria was reported from Boston 1 Cambridge, 4; Fall River 3; Foxboro, 5; Lawrence, 5; Lynn 1; Marlboro, 1; New Bedford, 1; North Andover 1; Revere, 2; Taunton, 1; Worcester, 3 total 28.

Dysentery bacillary, was reported from Arlington 1; Beverly 5; Boston, 1; Cambridge, 11; Chelmsford 1; Danvers, 12; Fall River, 2; Lowell 1; Lynn, 1; Malden 5; Medford, 69; Newton 2; Palmer 3; Russell, 1; Salem, 3; Waltham 4; Watertown 1; Westport, 3; Wrentham, 9 total, 135.

Malaria was reported from Boston 1 total 1.
Meningococcus meningitis was reported from Brockton, 1; Cambridge, 1 total 2.

Paratyphoid B fever was reported from Woburn 1 total, 1.

Pellagra was reported from Boston 1 total 1.
Pfeiffer bacillus meningitis was reported from Wakefield, 1; Worcester 2 total, 3.

Septic sore throat was reported from Boston, 3; Brookline, 1; Cambridge, 1; Malden 2; Merrimack, 1; Somerville, 1; Williamstown 1 total 10.

Trachoma was reported from Boston, 2; Cambridge, 1; Worcester 1 total, 4.

Trichinosis was reported from Ayer, 1; Boston 1 total, 2.

Typhoid fever was reported from Cambridge, 1; Saugus, 1 total, 2.

Undulant fever was reported from Beverly 1; Dighton 1; Gloucester, 1; Leverett, 1; North Adams, 1 total 5.

Diphtheria for the eighth consecutive month showed a higher reported incidence than for the corresponding month of the previous year.

Lobar pneumonia after four low months, showed an increase to slightly above the five year average.

Sonne (bacillary) dysentery continues to be reported at an unusually high level. All parts of the state have

been involved, with a concentration of reported cases in the Metropolitan Boston area.

Typhoid fever was reported at a record low level.

For the fifth consecutive month the reported incidence of scarlet fever reached a new low.

The reported incidences of pulmonary tuberculosis and tuberculosis (other forms) were well within the five year average.

Measles continued in its seasonal upswing reaching the highest reported November level for the previous five years.

There was nothing noteworthy about the reported incidences of anterior poliomyelitis, meningococcus meningitis, paratyphoid B fever, undulant fever, whooping cough, chickenpox, German measles and mumps.

REPORTS OF MEETINGS

BOSTON CITY HOSPITAL

On November 9, 1939 at the Boston City Hospital, Dr. A. C. Williams of the House Officers' Association presented Dr. George Crile, of Cleveland who discussed "Hypertension Can It Be Cured?" The importance of the problem is indicated among other things, by the actuarial statistics of several large insurance companies which show that fifty cents of each dollar paid in the past few years has been for deaths from hypertension and coronary and cardiovascular diseases.

Dr. Crile's unique approach to the subject resulted from his investigation of the explosion ten years before of some x-ray films which had been brought about by only a slight temperature rise. That led to a comparison of explosives, x-ray film, and protoplasm as regards composition. He concluded that the last was much like the other explosives qualitatively and was in a constant state of nitro-dinitrogenation influenced largely by the thyroid and adrenal glands.

Dr. Crile then undertook a ten year research into the reason for the susceptibility of the "civilized" person to certain degenerative diseases practically, if not entirely unknown to native tribes and animals. Over thirty-five hundred animals were obtained and weighed in toto, and their various organs were then weighed individually. It was an attempt fundamentally to determine wherein lay the "intelligence, personality and energy of man," and at tenness was directed primarily at the brain, sympathetic nervous system, adrenal glands and thyroid gland. The speaker had pictures demonstrating the gradual increase in size of these organs through the phylogenetic scale, with a great step forward being noted between the cold- and warm-blooded animals. This was not considered surprising since it has been estimated that 75 per cent of the daily food intake is used merely for the maintenance of the warm-blooded state. By far the largest celiac plexus was found in the lion and tiger which have developed this in response to their need for power and alertness for the "supreme effort" which characterizes their survival. Dr. Crile concluded from his exhaustive study that the size of the brain is proportional to the environmental temperature, its greater part being used for "sparking the body metabolism."

Although man did not head the list in regard to size of the celiac plexus, the ratios of the weights of the brain, thyroid gland and adrenal glands to the body weight showed him far in the lead. Thus, Dr. Crile believes, is the reason man is the world's most energized being and is one of the reasons for man's place in nature. Another factor is his unique ability to control his body heat by virtue of his great body surface, lack of natural body covering and unique faculty for sweating all over.

Furthermore, man was the only animal in whom the ratio of thyroid weight to the total body weight surpassed the adrenal ratio. Consequently he is not endowed with the tremendous capacity for energy outbursts of some of his animal counterparts but is instead a walking, thinking being with the singular and often undesirable tendency to work all day and worry all night.

Then Dr Crile attempted to determine whether animals obeyed any physical laws in regard to their metabolism. The only correlation following any such law was between the brain weight and the amount of energy produced in twenty four hours. Man and to a lesser degree the primates, were the only exceptions to the law, and since Benedict has ruled out mental processes as contributing any significant amount to human metabolism, this was taken as another indication that man really has a unique place in nature. The speaker considered this somewhat of an 'anatomical I Q' for man. The only drive peculiar to man is his thinking brain, and this may be the force, through the thyroid and adrenal glands, which causes diseases specific for civilized man.

The next step was the correlation of this natural history with the problems of cardiovascular disease which had prompted the extensive research. Dr Crile corroborated the well known fact that the larger size of the brain in civilized man is due to its increase in the 'thinking portion' of the organ over that of the aborigine. However, there was a concomitant increase of the thyroid and adrenal glands, and it was the size of the latter and the celiac plexus which attracted the attention of Dr Crile. Consequently, the weights of the ganglia were compared in known hypertensive states and in various other conditions. The preponderance of greater weights in the former disease was marked. This, then, concluded the speaker, was a point of attack on hypertension, an opportunity to correct the pathologic physiology by interruption of the anatomical pathway.

A total of 256 patients have been subjected to celiac ganglionectomy. Particular attention was focused on their early lives. It was found that their childhood differed from that of eventual thyrotoxic patients but that both were far different from normal children. Both groups were found to have been high tension, tireless children with many activities and ambitions. Those who later showed hyperthyroid tendencies, however, were, on the average, far superior academically. In both groups the people themselves seldom became fatigued but the integral parts wore out.

At first, the number of operative and postoperative fatalities made the success of the procedure questionable. With additional experience, however, Dr Crile and his associates have completed the past 127 cases without an operative death. The early misfortunes resulted from the technical difficulties of the procedure itself, the fall of the blood pressure to zero in some instances, and the permanent anuria from long-continued hypotension. To combat these complications, it was decided to give continuous intravenous glucose in distilled water, and perform the operation slowly and with meticulous care.

The average results three years postoperatively proved promising, stated Dr Crile, for the average blood pressure had fallen from 213 systolic, 130 diastolic, to 187, 116. The fine results in many instances, however, were neutralized by the failures in improperly selected cases. At that time there were no adequate criteria for operability, even those who had had apoplectic attacks being included. In spite of that, however, 55 per cent survived three years or more and 82 per cent returned to work, many in spite of lack of objective improvement. There was symptomatic relief in 88 per cent of cases, and this, Dr Crile opined, was due

to a damping of the patient's 'innate' drive, in spite of the progression of the already existing arteriosclerosis in many patients. In fact, it was doubtful in such cases if there was any prolongation of life. But just the relief from symptoms, which the speaker said he had come to realize were worse than those ascribed to terminal cancer, was considered a justification for the ganglionectomy. The decrease in cardiac deaths from 60 to 12 per cent was considered an indication for further study in the same direction.

Dr Crile's final suggestion was for an attempt at the prevention of hypertension by recognizing the children possessing the innate tendencies. These children should not be allowed to skip grades at school and engage in outside activities but should rather be urged to enjoy life in a wholesome way. The speaker stated that satisfaction of ambitions merely allows the inborn driving force with in the brain to cause hyperfunction of the sympathico-adrenal system, with resultant hypertension. It was pointed out that those practicing the Chinese philosophy in its classic form have practically no hypertension as compared with their countrymen in Hong Kong.

In discussion, Dr A. R. Kimpton asked if renal omentopexy might not be beneficial following the operation, in order to help the already damaged kidney. Dr Crile replied that such was an excellent idea.

A physician asked whether these patients lost their entire energy. But Dr Crile assured him that such was not the case, citing the instance of a successful surgeon who was still carrying on, albeit somewhat more slowly, after the removal of the largest celiac ganglion ever weighed. He said that there is a subjective loss of a certain drive, but the presence of a large initial amount makes the final result entirely acceptable.

NOTICES

BOSTON CITY HOSPITAL

The monthly clinicopathological conference will be held at the Boston City Hospital on Wednesday, January 10, at 12 o'clock noon, in the Pathological Amphitheater.

JOSEPH E. HALLISEY, M.D., *Secretary*,
Medical Staff

SOUTH END MEDICAL CLUB

The next meeting of the South End Medical Club will be held at the headquarters of the Boston Tuberculosis Association, 554 Columbus Avenue, Boston, on Tuesday, January 16, at 12 o'clock noon. Dr Siegfried J. Thannhauser will speak on 'Obesity'.

Physicians are cordially invited to attend.

JOHN B. HALL, M.D., *Secretary*

PETER BENT BRIGHAM HOSPITAL

A research conference of the medical staff of the Peter Bent Brigham Hospital will be held in the amphitheater of the hospital on Tuesday, January 9, at 5 p.m.

PROGRAM

The Observations of Diuresis Produced by Hypertonic Sugar and Polyhydric Alcoholic Solutions.
Dr Philip Grabfield.

Toxemia of Pregnancy. Dr Lewis Dexter.

A joint medical and surgical clinic at the Peter Bent Brigham Hospital will be held on Wednesday, January 10,

from 2 to 4 p.m. Drs. Soma Weiss and Elliott C. Cutler will speak on "Chills." A clinicopathological conference conducted by Dr. Elliott C. Cutler will take place from 4 to 5 p.m.

On Thursday, January 11 from 8.30 to 9.30 a.m. there will be at the Peter Bent Brigham Hospital a combined clinic, conducted by Dr. Soma Weiss of the medical surgical, orthopedic and pediatric services of the Children's Hospital and the Peter Bent Brigham Hospital.

Physicians and students are cordially invited to attend.

TUMOR CLINIC BOSTON DISPENSARY

Each Tuesday and Friday morning 10.00 to 12.30 there is a meeting of the Tumor Clinic of the Boston Dispensary a unit of the New England Medical Center. Neoplasms of various sorts are seen and discussed and when there is an indication are treated with radium of high voltage x-ray. Physicians are invited to visit this clinic. They may bring patients for aid in diagnosis or may refer patients to the clinic following which a report will be returned to the referring physician. A limited number of beds are available for diagnostic study and for treatment.

BOSTON DOCTORS SYMPHONY ORCHESTRA

The Boston Doctors Symphony Orchestra will rehearse under Alexander Theide, former concert master with the Cleveland Symphony Orchestra and the Philadelphia Symphony Orchestra every

Thursday at 8.30 p.m., in Studio A Station WMLX 70 Brookline Avenue, Boston. Those interested in becoming members should communicate with Dr. Julius Loman Pelham Hall Hotel Brookline (BEA 2430).

HARVARD MEDICAL SOCIETY

The next meeting of the Harvard Medical Society will be held on Tuesday January 9 in the amphitheater of the Peter Bent Brigham Hospital (Shattuck Street entrance) at 8.15 p.m.

PROGRAM

Presentation of cases.

The Mechanism of Secretion in the Adrenal Gland.
Dr. H. Stanley Bennett.

Medical students and physicians are cordially invited to attend.

ROBERT M. ZOLLINGER, M.D. Secretary

UNITED STATES MARINE HOSPITAL

The staff meeting of the United States Marine Hospital, Chelsea, Massachusetts will be held at "The Hut," on Friday afternoon, January 19 at 4.00. Dr. H. Houston Merritt will talk, his subject being "Syphilis of the Central Nervous System."

JOHN W. TRASK, Medical Director in Charge

SECOND ANNUAL CONGRESS ON INDUSTRIAL HEALTH

The Second Annual Congress on Industrial Health sponsored by the Council on Industrial Health of the American Medical Association will be held at the Palmer House Chicago on Monday and Tuesday January 15 and 16.

The congress will have a morning and afternoon session devoted to special topics each day. "Syphilis in Industry" will be discussed at the Monday afternoon session. "Physical Examination" on Tuesday morning and "Disability Evaluation" on Tuesday afternoon.

A dinner and round-table discussion on "Organization and Activities of Committees on Industrial Health in State and County Medical Societies" will take place on the first evening, January 15.

SOCIETY MEETINGS AND CONFERENCES

CALENDAR OF BOSTON DISTRICT FOR THE WEEK BEGINNING MONDAY JANUARY 8

MONDAY JANUARY 8
12.15 p.m.-1.15 p.m. Clinicopathologic conference. Dr. S. Burr Wolbach. Peter Bent Brigham Hospital amphitheater.
4 p.m. Physics and medical students are cordially invited to attend clinic presented by the medical, surgical, and orthopedic services of the Children's Hospital in the amphitheater of the Children's Hospital.

TUESDAY JANUARY 9
9-10 a.m. Certain Hematological Problems. Dr. W. Dameshek. Joseph H. Pratt Diagnostic Hospital.
10 a.m.-1.30 p.m. Boston Dispensary tumor clinic.
12.15 p.m.-1.15 p.m. X-ray conference. Dr. Merrill C. Sosman. Peter Bent Brigham Hospital amphitheater.
5 p.m. Research conference of the medical staff. Peter Bent Brigham Hospital.
8.15 p.m. Harvard Medical Society. Peter Bent Brigham Hospital (Shattuck Street entrance).

WEDNESDAY JANUARY 10
9-10 a.m. Hospital case presentation. Dr. S. J. Thannhauser. Joseph H. Pratt Diagnostic Hospital.
12 m. Clinicopathological conference. Children's Hospital amphitheater.
12 m. Monthly clinicopathological conference. Pathological amphitheater. Boston City Hospital.
2 p.m.-4 p.m. Joint medical and surgical clinic. Peter Bent Brigham Hospital.

THURSDAY JANUARY 11
8.30 a.m.-9.30 a.m. Combined clinic of the medical, surgical, orthopedic and pediatric services of the Children's Hospital and the Peter Bent Brigham Hospital at the Peter Bent Brigham Hospital.
9-10 a.m. The Place of Electrocardiography in Clinical Diagnosis. Dr. J. M. F. Kner. Joseph H. Pratt Diagnostic Hospital.

FRIDAY JANUARY 12
9-10 a.m. The Present Day Specific Treatment of Pneumonia. Dr. Maxwell Finland. Joseph H. Pratt Diagnostic Hospital.
10 a.m.-12.30 p.m. Boston Dispensary tumor clinic.

SATURDAY JANUARY 13
9-10 a.m. Hospital case presentation. Dr. S. J. Thannhauser. Joseph H. Pratt Diagnostic Hospital.
10 a.m.-12 m. Medical staff rounds of the Peter Bent Brigham Hospital. Conducted by Dr. Soma Weiss.

SUNDAY JANUARY 14
4 p.m. Serious Accidents What to do and what not to do. Dr. Charles C. Lund. Free public lecture. Harvard Medical School amphitheater of Building D.

*Open to the medical profession.

BOOK REVIEWS

Functional Disorders of the Foot Their diagnosis and treatment Frank D Dickson and Rex L Divele
305 pp Philadelphia, Montreal and London J I Lippincott Co, 1939 \$5 00

The authors of this text very justly point out that the prevalence and economic importance of foot disorders are not sufficiently appreciated by the medical profession, that the profession treats them too indifferently, and that a large portion of the public has grown to consider the ailments as lying more directly in the province of such lay groups as chiropractors and shoe salesmen rather than in that of the family doctor. Unfortunately, there is altogether too much truth in these assertions. To help remedy the situation, this text is aimed principally as a guide for the practicing physician toward a clearer understanding of common foot disorders. Secondly, the authors seek to offer the non-medical practitioners an exposure of 'the primary causes of foot disorders and their legitimate limitations in carrying out treatment.' With this in view, it is explained that "only such material on the evolutionary development of the foot, on anatomy and on physiology has been introduced as seemed necessary to an intelligent understanding of the foot as a functioning organ." The aim which is thus expressed has been carried out most successfully, without limiting the completeness of the study.

The general causes of foot imbalance are first analyzed and then succeeding chapters are devoted to the special influence of the three age groups—children, adolescents and adults. As the etiologic factors are considered, the clinical applications are described in sections devoted to symptoms, exercises and treatment. A special chapter deals with "foot apparel," another to foot strapping, and one to examination of the foot. There are also chapters discussing the common affections of the foot in the skin, nails, heel and hallux.

In general, the great value of this book lies in the intelligent evaluation which it places on various methods of treatment. It does not adopt any iron-clad radical conservative rule, but reviews the various available corrective measures and selects that which is best suited to the particular type of case, whether by shoe corrective manipulation, stretching or operative procedure.

Studies from the Rockefeller Institute for Medical Research Vol 112 600 pp New York The Rockefeller Institute for Medical Research, 1939 \$2 00

Of special interest in this volume is the study by Ro and Kidd comparing the virus-induced rabbit tumors with the tumors induced by the application of coal tar. There is a striking similarity between both types of papilloma.

An interesting and carefully studied case of periarteritis nodosa is presented by Emerson and others. A study by White brings out the potentially unlimited growth of incised plant callus under artificial conditions.

The Story of a Baby Marie H Ets 63 pp New York The Viking Press, 1939 \$2 50

The author tells the story of a baby in a manner which will appeal to parents who wish enlightenment on a problem of this sort. It may also be read with much interest by high-school students and by laymen in general.

NUMBER 2

CARDIO-OMENTOPEXY IN THE TREATMENT OF ANGINA PECTORIS*

Report of Two Cases

JOHN W. STRIEDER, M.D.,† HOWARD M. CLUTE, M.D.,‡ AND
ASHTON GRAYBIEL, M.D.§

BOSTON

CORONARY arteriosclerosis, with its major complication, coronary thrombosis, is one of the major causes of serious heart disease which all too frequently attacks men in the prime of life whose other organs are still intact and healthy. We neither understand the factors involved in the onset of this arteriosclerotic process nor can we control its progress. Furthermore, medical treatment for these cases is either of no value or at best but palliative. It is no wonder, then, that many have turned to surgery to seek some direct means for increasing the blood supply to the myocardium.

Any method, therefore, whose principle is the improvement of the coronary circulation by surgically establishing a new blood supply to it is worthy of serious consideration and trial. Such a principle has been evolved and carried out in this country by Beck¹ and in England by O'Shaughnessy², and although the principle of surgical revascularization followed by both has been the same, each surgeon has used different methods. Beck has developed a new blood supply to the heart by grafting to it a portion of pectoral muscle, whereas O'Shaughnessy has utilized a pedicled omental graft. To discuss all the voluminous clinical and experimental data bearing on this subject is beyond the scope of this report but certain studies may be cited.

It is of course well known that attempts have been made for many years to improve the lot of the patient suffering from angina pectoris by an indirect surgical approach to the problem. These efforts have not been attended by notable success,

so that operations on the sympathetic nervous system, which were at first encouraging, have since been demonstrated to be of little permanent value, and have been largely abandoned. For the same reason total thyroidectomy, designed for a similar purpose, has fallen into disuse.

Of recent years the clinical importance of the collateral blood supply to the heart has been emphasized by Hudson, Moritz and Wearn.³ From their work it would appear that coronary occlusion is compensated for by channels from the remainder of the coronary circulation as well as by collaterals from the mediastinal circulation. The latter circulation includes connections to the coronary circulation from the pericardiophrenic artery and the anterior mediastinal, pericardial, bronchial and esophageal branches of the aorta.

As has been stated by O'Shaughnessy,² it is clear that in many cases this collateral circulation is insufficient and that an infarcted area in the myocardium may go on to rupture within a few days, or may form a cardiac aneurysm which will sooner or later rupture from necrosis. In other cases a badly crippled heart is the result of the myocardial ischemia.

In cases where death does not follow coronary occlusion within a short time, the necessity for a compensatory and sufficient circulation to the myocardium is obvious. Although Spalteholz⁴ has shown a rich anastomosis between the right and left coronary trees, Leriche⁵ has demonstrated experimentally that the efficiency of the collateral supply from the coronary system is a direct function of the state of the systemic blood pressure. And, also in this connection, Mautz and Beck⁶ have recently shown a considerable variation in the degree of intercoronary anastomosis in the normal heart.

Utilizing a new technic of injection and dis-

*From the Division of Thoracic Surgery and the Evans Memorial, Massachusetts Memorial Hospitals.

†Instructor in thoracic surgery, Boston University School of Medicine; assistant in surgery, Harvard Medical School; visiting surgeon, Massachusetts Memorial Hospitals, Boston.

§Instructor in medicine, Boston University School of Medicine; cardiologist, Massachusetts Memorial Hospitals.

section, Schlesinger⁷ has recently shown that anastomoses develop readily whenever and wherever arteriosclerotic narrowing or occlusion causes obstruction in the coronary artery circulation. These anastomoses are localized to the regions where they are needed. He concludes, moreover, as a result of these studies: "The coronary arteries, in *normal* human hearts, even senile hearts, are true Cohnheim end arteries, without anastomotic connections, such anastomoses do not develop *pari passu* with increase in age."

As regards the collateral extracoronary sources of blood supply, it has long been known that pericardial adhesions may be effective in the conduction of such new channels to the heart. Thus, Beck, Tichy and Moritz,⁸ who experimentally produced broad areas of adhesions between the heart and the pericardium of dogs, found that the animals were able subsequently to survive almost complete occlusion of both coronaries through the use of silver bands. In man there is also convincing evidence which tends to corroborate the fact that visceroparietal pericardial adhesions efficiently aid the circulation to the heart. The formation of such adhesions in a given case of coronary occlusion, however, would seem to be a purely fortuitous circumstance. This is borne out by the autopsies on 83 cases of coronary occlusion reported by Parkinson and Bedford,⁹ in which there were but 11 cases of pericarditis. Injection studies by Hudson, Moritz and Wearn⁸ demonstrated the vascular connection between myocardium and pericardium when such adhesions existed.

From the foregoing experimental and other data, then, it would seem that if the heart muscle is to survive in some cases of coronary occlusion, sooner or later a rich blood supply, in the form of a collateral circulation, must become available to the myocardium. We have seen that such a compensatory circulation may form in the natural history of the disease. Indeed, as has been stated by Hochrein¹⁰: "We have learned to recognize that pericarditis is not a complication of coronary thrombosis but a natural attempt at healing—its presence is to be welcomed rather than deplored."

When adhesions do not form as a natural sequence, and when there is myocardial impurment as manifested by symptoms of cardiac ischemia, it would be desirable if the theoretical possibility of establishing such adhesions, and thereby improving the collateral circulation, could be brought to a practical clinical application. This has been effected by surgeons in this country and in Europe.

To Beck must go the credit for being the first surgeon to make an attempt at revascularization of

the ischemic heart in the human subject. He had observed that adhesions were capable of carrying blood to the human heart when he divided such adhesions at operation and found that they bled profusely. He was also familiar with the published data of cases where death was due to other causes, in which the heart was found to have both coronaries completely occluded and pericardial adhesions were present. As a result of these and other experimental observations, Beck, using the pectoralis major muscle as a pedicled graft, attempted to bring a new blood supply to the heart in a human subject. In this he was notably successful, his first patient, a totally incapacitated farmer, operated on in February, 1935, being able to return to physical labor, free of pain, after a suitable postoperative period.

At the same time, in London, O'Shaughnessy was proceeding with experiments on cardiac grafting. Instead of muscle he used a pedicled omental graft. It has long been recognized that the omentum is the only structure in the body with the specific property of vascularization, and as a result of his accumulated experimental evidence as to the vascularizing power of the cardio-omental graft, O'Shaughnessy was convinced of its superiority over other structures available for the same purpose. Beck had also used the omentum as a graft in experimental animals.

In 1936 O'Shaughnessy published the results of a series of omental grafts in the racing greyhound. In the paper he showed that greyhounds which had previously been subjected to ligation of the left coronary artery and to a cardio-omentopexy were able to chase the electric hare around a full course (526 yards) without distress. By injection methods he demonstrated conclusively the vascular connections between the grafts and the coronary trees of the animals. Grossly, these were manifested by the appearance of the injection mass at the orifices of the coronary arteries when the sole vascular attachment to the heart was the omental graft through which the injection was made. Histologically, the new vessels were shown to extend to the deeper branches of the coronary artery, even under the endocardium.

In 1938 O'Shaughnessy reported on 20 human cases. In this series the patients selected for operation showed what he considered to be unequivocal evidence of cardiac ischemia and had failed to benefit by medical treatment. Fifteen of these patients were suffering from angina pectoris, and of these 10 received cardio-omentopexy, 3 pericardiectomy with insertion of an irritant (aleuro-nat), 1 cardiopneumonopexy, and 1 died on the table before the operation was fairly begun. There

were 5 deaths, only 1 of which was the direct result of operation. The other 4 occurred two months or more after operation as a result of uremia, pulmonary infarct, pneumonia and empyema, and 'no apparent cause,' respectively. Of the 10 patients who survived, 8 enjoyed freedom from angina, and 7 of the latter returned to work.

O'Shaughnessy has thought that the control of postoperative shock is an easier matter following cardio-omentopexy than following Beck's operation, because of the extensive dissection of the pectoral muscles which is a necessary preliminary to the latter procedure. Moreover, the operation is less time-consuming, and, other factors being equal, the omentum is obviously a better vascularizing agent than is the pectoralis major muscle.

Because of these various considerations, we have concluded that cardio-omentopexy, when feasible, is the operation of choice for the establishment of a new blood supply to the heart by surgical means. We have performed it in the two cases to be reported.

SELECTION OF CASES FOR OPERATION

As may have been gathered from the foregoing discussion, no hard and fast indications for the selection of cases for operation have as yet been outlined. The final decision as to suitability for operation must rest with the cardiologist. From the surgeon's viewpoint, patients with angina are notoriously bad risks for operation by virtue of the very condition for which it is to be performed. This aspect, therefore, is a constant when arriving at a decision.

Other than this, however, we have insisted upon the fulfillment of several requirements. In so far as it is possible to determine, there must be, first, indisputable evidence of coronary heart disease with angina pectoris. Strict observance of this rule will we believe, supply the necessary base line for the evaluation of the operation as a therapeutic measure. We insist, at present, that the patient be under sixty years of age and not obese. Serious complications in other organs are, of course, contraindications. We have rejected, and will continue to reject, patients with marked hypertension and cardiac enlargement.

If the patient fulfills the foregoing requirements, he is observed during a control period of one month, during which time exercise-tolerance and other tests are made.

We also are of the opinion that patients who give evidence of congestive failure are not suitable candidates for operation. Beck operated on a man in failure. He simply performed pericardi-

ectomy and introduced powdered beef bone for the purpose of increasing intercoronary communications or adding new capillary anastomoses from the pericardial fat. This patient stood the operation, but remained in failure and died four months later. Apparently the operation did nothing, one way or the other. We agree with Beck that the patient with coronary disease who is in failure is not a suitable person for operation.

With these patients the problem of weighing the immediate risk of operation against the prognosis without operation is a particularly difficult one. This is due to the fact that, as yet, time and the number of cases have not permitted an imposing array of figures from which to draw conclusions, and also to our inability to offer on the basis of the evidence at hand a sound prognosis in the absence of operation.

O'Shaughnessy has enlarged the scope of his indications to include 5 cases of non anginal cardiac ischemia but at the time of reporting, the operations had been too recently performed for conclusions to be drawn. There was 1 death, and 1 patient was able to return to work.

At the present time O'Shaughnessy¹¹ believes that cardio-omentopexy is relatively safe in the following circumstances:

A lapse of about six months after an attack of coronary thrombosis in patients with a clear previous history who are aged forty five to fifty five.

Specific aortitis with angina, provided the heart is not enlarged to any great extent.

Hypertensive heart failure, with the same proviso.

However, at least for a time, we prefer to confine ourselves to the narrower indications given earlier and limit our operations to patients having unrelievable angina pectoris.

TECHNIC OF OPERATION

Our procedure has been as follows when operation is decided on. For several days prior to operation the patient receives 3 gr. of quinine sulfate three times daily, in order to reduce the irritability of the heart. Morphine sulfate is given in suitable doses preoperatively. After induction of anesthesia with ether vapor and oxygen an intra tracheal tube is introduced and connected to the anesthesia machine in a closed system so that differential pressure may be used.

The patient is placed in the dorsal recumbent position and an incision is made over the fifth left intercostal space extending from the mid sternal line to the anterior axillary line. The left pleural cavity is entered through the fifth interspace, and after the fifth and sixth cartilages have been divided at the chondrosternal junctions

(Fig 1) the Sauerbruch rib-spreader is placed. The left lung, if free of adhesions, will drop posteriorly as it collapses and allow an ample view of the pericardium (Fig 2).

The phrenic nerve is identified on the pericardium and crushed lightly for the width of a

great importance to avoid penetrating the entire wall of the ventricles.

When the omentum is widely covering the left lateral aspect of the ventricles, its edges are sutured to the cut edges of the pericardium and also to the inferior pericardiosternal ligament (Fig 4).

The lung is next reinflated and the wound in the chest wall is closed in layers in the usual airtight manner, employing interrupted perichondral

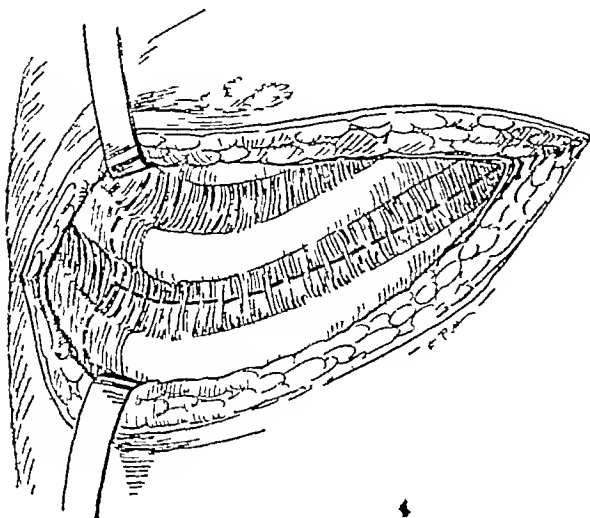

FIGURE 1

This drawing illustrates the line of incision in the fifth left intercostal space. The cartilages are divided close to the sternum.

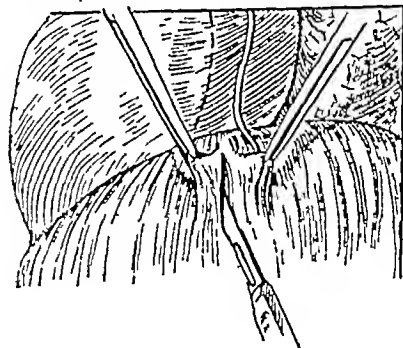

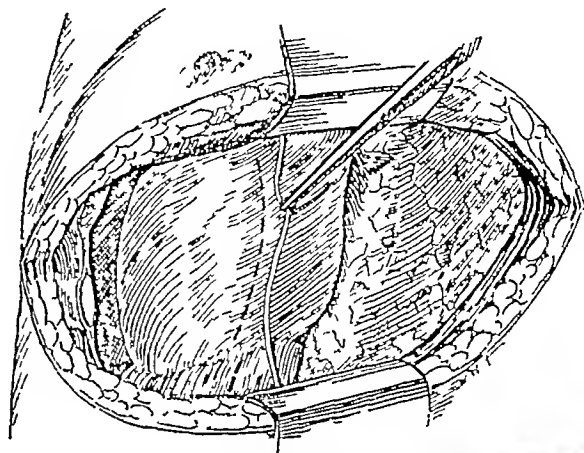

FIGURE 2

In this drawing the ribs have been retracted and the lung has fallen backward, exposing the pericardium. The phrenic nerve is being pinched as it lies on the pericardium. The dotted line indicates the incision to be made in the pericardium and the direction of the incision in the diaphragm. The insert shows the diaphragm being incised, when it has risen into view after paralysis of the left phrenic nerve.

hemostat. This causes the left hemidiaphragm to rise into view (Fig 2).

An opening is then made through the diaphragm in the direction of its fibers reasonably close to the pericardium and 5 cm long. Through this opening the fingers deliver a suitable piece of omentum for attachment to the heart muscle. It is desirable that the omentum be pulled up until its lower margin can be obtained, and not grasped near the colon. Care must be used that undue tension on the transverse colon is avoided. The colon must not enter or encroach on the diaphragmatic opening (Fig 3).

When sufficient omentum has been delivered through the diaphragm to cover the area of myocardium to be grafted, steps must be taken to close the diaphragm about the omentum and to prevent a later herniation of abdominal organs into the pleural cavity. In each of our cases we placed many interrupted silk sutures about the opening in the diaphragm in order to include the omentum and shut off the pleural cavity.

The pericardium is next opened (Fig 3), and the omental graft is sutured to the heart muscle with interrupted silk sutures placed over its flat surface. The graft should be placed so as to overlap the branches of the right and left coronary vessels. Care must be taken to include no branches of the coronary vessels in the sutures. It is of

braided-silk sutures. At the conclusion of the operation, as in any intrathoracic procedure, it has been our practice to insert a needle and withdraw any trapped residual air from the pleural cavity, thus adjusting the inspiratory and expiratory pressures to their normal negative levels.

POSTOPERATIVE COURSE

The postoperative course has been remarkably uneventful in our two cases. We believe it important to maintain the blood pressure at a constant optimum level, in order to prevent stagnation and thrombosis in the coronary circuit, and to that

end the pressure is observed at very frequent intervals (every five to fifteen minutes) during the immediate postoperative hours. If the pressure shows any tendency to fall, 0.2 cc. of 1:1000 adrenalin solution is administered hypodermically. Quinidine sulfate is continued by mouth.

The pulse is usually paradoxical for a few days, and there may be irregularities of varying degree. Continuous nasal oxygen is administered, and the water balance is maintained by proper amounts of suitable fluids given parenterally. Fluid may accumulate in the chest, and if embarrassing to the patient may be removed.

COMPLICATIONS

In our first case, diaphragmatic hernia, from which acute obstructive symptoms arose, necessi-

in a case in which grafting had been performed two years previously. The patient, a woman, had died from chronic alcoholism with neurological and psychological symptoms, but apparently the diaphragmatic hernia had never given trouble. In our case the fundus of the stomach was incarcerated,

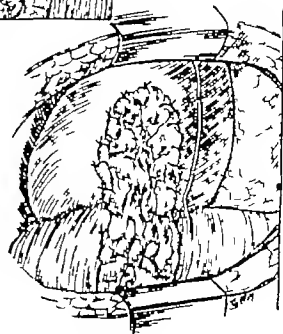

FIGURE 4

The insert shows the surface of the omentum being sutured to the myocardium with multiple silk sutures avoiding the branches of the coronary vessels. The lower drawing shows the suturing of the graft to the myocardium completed. Note the cut edges of the pericardium sutured to the omental graft in order to encourage further vascular anastomosis.

FIGURE 3

The insert shows the incision in the pericardium. Usually the tense pericardium retracts markedly thus exposing the heart. A suitable portion of omentum has been drawn through the diaphragm into the thorax. The dotted lines indicate the mattress sutures from side to side in the diaphragmatic incision through the substance of the omentum. The ends of the incision in the diaphragm have been sutured to bring it snugly about the omentum.

tating operative intervention, occurred six months after cardio-omentopexy and resulted in death. O'Shaughnessy¹¹ states that this complication has never been observed in any of his experimental animals, but that a hernia was found at autopsy

and the patient was having bloody vomitus when he re-entered the hospital. The hernia was reduced and repaired by the abdominal route, but the patient died forty five minutes after his return to the ward.

Certainly the technic of this operation must be seriously concerned with the prevention of post-operative diaphragmatic hernia, as well as with the attachment of omentum to the heart. We intend to do two things in the future to prevent such herniation. First, we shall do more careful suturing of the omentum to the diaphragm and of the ends of the incision in the diaphragm, since it seemed to us that in our first case the hernia opening in the diaphragm at autopsy was much larger than the original incision. Second, we in-

tend to run several crisscross silk sutures through the substance of the omentum placed in such a way as to include the sides of the opening in the diaphragm (Fig 3). We shall not tie these sutures tightly enough to embarrass the circulation in the omentum. We expect that their presence will prevent herniation through the diaphragm.

In spite of presumably ample preoperative medication, the excitement and apprehension effected by bringing the second patient to the operating floor precipitated a severe attack of angina pectoris. Because of this it was necessary to postpone the operation for a week. The patient was not informed of the date set for operation, he was given Avertin by rectum in bed and brought to the operating room unconscious, after the manner of a "thyroid steal." The operation was performed without incident.

RESULTS OF OPERATION

O'Shaughnessy has now done fifty grafts but states that he will make no statistical analysis until he has done one hundred. His last reported series has been previously mentioned.

Beck, using pectoral muscle grafts, has operated on 25 patients. Of these, 16 are living and 9 are dead. The mortality rate in the first 12 cases was 50 per cent, and in the last 13, 15 per cent. Thirteen patients were observed for five months or longer after operation. There were no patients who were not improved by operation. Three had no pain, required no medication and had definitely increased exercise tolerance. Nine had pain, which was less severe, and took occasional medication, and the exercise tolerance was increased. One had some relief of pain and a slight increase in exercise tolerance.

In our two cases, whose histories follow, there was no operative mortality. The first patient died six months after cardio-omentopexy as a result of the repair of the diaphragmatic hernia. Following the primary operation he had had great relief from pain, required no drugs and showed a marked improvement in exercise tolerance.

The second patient has now lived for thirteen months since operation. He still has pain, which is less severe, requires some medication and has a greatly improved exercise tolerance. O'Shaughnessy states that improvement may be expected for twelve to eighteen months after operation.

CASE REPORTS

CASE 1 C W, a 44 year-old, Swedish salesman, was admitted to the Evans Memorial on May 18, 1938. For the previous 2 years he had had substernal pain and oppres-

sion. During the last 6 months he had noted that less and less exertion produced the pain, so that eventually he could not walk across the street without having any. The electrocardiogram showed changes consistent with coronary heart disease, and there was suggestive evidence of an old infarction. The patient was transferred to the Division of Thoracic Surgery and on June 8, cardio-omentopexy was performed, uneventfully. The postoperative period was remarkably smooth and he was returned to the Evans Memorial for further medical observation on June 30. He was gradually allowed activity and was discharged to his home July 30.

From this time onward there was a progressive improvement in the exercise tolerance, so that about September 1, the patient was able to return to part-time work. He had some pain, but it was minimal, and a great deal more effort was required to bring it on. He boasted about his "new heart" to his friends. About October 1, he first noted discomfort after eating. About December 1, he had fullness in the left upper quadrant after every meal, with cramp-like pain radiating through to the left scapular region. He re-entered the hospital December 25 with evidence of acute gastric distress, vomiting some bloody mucus. It seemed evident that he had high obstruction, probably due to herniation through the diaphragm.

After suitable preparation, the patient was operated on December 28. A laparotomy was performed and the proximal third of the stomach was found herniated through the hiatus created by the cardio-omentopexy. This was repaired easily and the patient was returned to the ward in good condition. He died suddenly 45 minutes after his return to bed.

Autopsy was performed by Dr. Charles Branch. Microscopical study of sections at the site of the graft showed a rich capillary growth from it into the myocardium. There was extensive fibrosis of the myocardium, with multiple areas of old infarction.

CASE 2 J K, a 53-year-old, Lithuanian, Jewish shoe maker, was admitted to the Evans Memorial on October 15, 1938. For approximately 1 year prior to entry he had been suffering from typical attacks of angina pectoris. He experienced some relief of his pain with nitroglycerin and medical measures until March, 1938, when he had an attack lasting for 15 minutes. Since that time the attacks had been more frequent and the pain had developed on less and less exertion. The electrocardiogram was typical of coronary heart disease and the exercise-tolerance test was low. The patient continued to have attacks of anginal pain of varying degree while in bed under observation.

The patient was accepted for cardio-omentopexy and was brought to the operating floor on November 6. However, excitement and apprehension precipitated an attack of paroxysmal auricular tachycardia with a resulting status anginosus, and the operation was postponed. On November 15, Avertin was instilled into the rectum while the patient was still in bed on the ward. He was then brought to the operating room and cardio-omentopexy was performed without incident.

Other than for some urinary retention, requiring constant drainage for a week, the postoperative period was entirely uneventful. The patient was transferred back to the Evans Memorial on December 5, and was discharged to his home, greatly improved, January 28, 1939.

He was last seen in November, 1939, at which time, he was improved as to exercise tolerance and as to the amount and frequency of his pain, and had returned to part time work.

SUMMARY AND CONCLUSIONS

The experimental and clinical basis for attempting revascularization of the ischemic heart is briefly considered.

The indications for and technic of cardio-omentopexy are presented, and the complications discussed.

Two cases in which cardio-omentopexy was performed are reported.

Many more patients must be operated on before any sweeping conclusions may be drawn, but on the basis of the work already done we are encouraged to believe that the principle of revascularization is sound. At the present time, we believe that we should be concerned with establishing the fact that an adequate blood supply can be brought to the heart, regardless of the method used. When this has been definitely shown to be possible and physiologically efficient in the human subject, the method will become important.

ACUTE PANCREATIC NECROSIS*

A Clinical Lecture

JOSEPH H. PRATT, M.D.†

BOSTON

I WISH to discuss a very interesting disease and to point out the advances made during the past decade in its diagnosis and treatment. I refer to acute pancreatic necrosis. I once heard Dr. Osler say that in presenting the subject of a particular disease to students it is always well to take an actual case as a text. Through the kindness of Dr. Putnam Kennedy, of the Boston City Hospital, I am able to follow this advice as I have before me the records of an instructive case which was studied there only a few weeks ago, and which through the courtesy of Dr. Soma Weiss I have permission to report. It illustrates most satisfactorily the newer knowledge in diagnosis and treatment.

CASE REPORT

The patient, a 43-year-old woman was admitted last October suffering from bronchial asthma, a pulmonary infarct and phlebitis of the left saphenous vein. During the latter part of her hospital stay she complained mildly of vague gas pains in the epigastrium. She was discharged in early November but readmitted on November 12, in a state of shock. The previous night she had felt sudden

severe pain in the midepigastrium followed by continuous vomiting of colorless thin fluid. Pain continued throughout the night, increasing in severity, and in the morning the vomiting became more severe. Pain radiated from the midepigastrium into both upper quadrants and later involved the entire abdomen and the midback. The patient was brought to the hospital in an ambulance and when seen on the admitting floor was apparently in extremis. She was well oriented and able to recognize her surroundings but rapidly became pulseless with an audible heart rate of about 80. On two occasions she stopped breathing but recovered after coramin and 50 per cent glucose had been administered intravenously.

Shortly after admission the pain extended to the cardiac area and to both shoulders. At physical examination the abdominal wall was thin and lax. There was no muscle spasm but great tenderness over the entire abdomen especially in the upper quadrants where it was more marked on the right than on the left. The rebound tenderness was most marked in the right upper quadrant. There was also tenderness over both shoulders. At 9 p.m. the temperature was 97.6 F, the respirations 28 and the pulse 70. The leukocyte count was 18,400. The urine was free from albumin and sugar and contained bile but no urobilinogen. The diagnosis on admission was "acute surgical abdomen" due either to a ruptured gall bladder or to acute pancreatic necrosis.

The following day, November 13, the temperature was subnormal. The urine still contained considerable bile. The urinary diastase was 256 units (Fig. 1). Dr. Stanley J. G. Nowak saw the case in consultation and noted tender

Delivered at the first meeting in the auditorium of the Joseph H. Pratt Diagnostic Hospital, December 6, 1938.

†Clinical professor of medicine, Tufts College Medical School; physician-in-chief, New England Medical Center, Boston.

ness in both flanks, especially in the left over the tail of the pancreas. This, together with the febrile response, the presence of bile in the urine and the improvement with conservative treatment, led him to make the diagnosis of acute pancreatitis. Dr Irving J. Walker agreed with this diagnosis, as did Dr Weiss, who noted maximum pain in the upper abdomen, particularly to the left just below the costal margin. On November 14 the urinary diastase fell to 64 units, which is the upper limit of normal. The icteric index was 5. The temperature rose to 100.6°F (axilla), and the pulse to 104. There was a trace of bile in the urine. After this date, bile was no longer present, but urobilinogen, first noted November 13, was found in increasing amounts until November 20. On November 16 there was still tenderness over the entire upper abdomen and in both flanks. The following day fluid was given

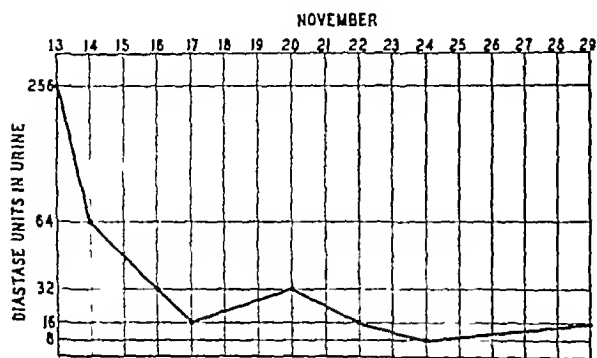

FIGURE 1

by mouth for the first time since admission, beginning with 1 teaspoonful of water every hour. The fasting blood sugar was determined for the first time that day and was 70 mg per 100 cc. The patient made a good recovery.

SYMPTOMS AND SIGNS

The first and most important symptom of acute pancreatic necrosis is pain. It is severe, often agonizing, not colicky but continuous and usually unrelieved by morphine. Moynihan¹ asserts that the pain is the most severe type of any resulting from abdominal disease and is attended with the most profound collapse. The location of the pain is significant. It is in the upper abdomen, usually in the epigastrium. Sometimes, as in the case reported, it extends across the entire front of the abdomen. It often radiates to the left back and occasionally, as here, to the midback. Brocq² maintains that the extension of the area of pain across the abdomen is an indication of an involvement of the entire pancreas, if the necrosis is confined to the head of the pancreas, the pain is to the right of the midline.

Vomiting accompanies the pain in almost all cases. This patient vomited repeatedly. When there is a great deal of hemorrhage into the pan-

creas, some blood may pass from the pancreatic duct into the duodenum and appear in the vomitus. Usually, however, as in this case, there is nothing distinctive in the character of the vomitus. On inspection the patient appears very ill. Sometimes there is cyanosis of the lips. There is a striking contrast between the severity of the condition and the scarcity of objective findings. At onset the temperature is normal and the pulse, although weak, may be little if at all accelerated. In a day or two moderate fever develops. There is tenderness in the epigastrium but no muscle spasm as a rule. A soft abdomen which permits deep palpation is characteristic. The location of the tenderness is often an aid in the diagnosis of acute pancreatic necrosis. The late Daniel F. Jones,³ one of our ablest diagnosticians, whose opinions were based on an unusually great experience with acute pancreatic necrosis, held that the most satisfactory aid in making the diagnosis was the careful determination of the location of tenderness. He wrote:

It is not enough to say there is tenderness in the upper abdomen. Given symptoms suggesting gall bladder disease, the diagnosis of pancreatitis should be made correctly in a high percentage of cases if there is tenderness extending to the left from the gall bladder. This can be accomplished only by meticulous care as to the amount and extent of the tenderness. Experience is necessary, of course, to make this distinction, and yet a former resident, of very moderate hospital experience, made a correct diagnosis in the next two cases that were admitted after he had been taught this method of diagnosis.

The clinical picture of what Dieulafoy⁴ calls *le diame pancréatique* has been drawn by many writers in different countries, and there is a striking similarity in their descriptions. An obese person of middle age addicted to alcohol and with a history suggesting cholelithiasis is suddenly seized shortly after a heavy meal with agonizing pain in the epigastrium, accompanied by vomiting. The pain continues, unrelieved by morphine, and vomiting persists. Signs of collapse appear. The temperature and pulse are not elevated. Aside from epigastric tenderness nothing of significance is found on examination of the abdomen. Symptoms continue many hours without abating.

Until the introduction of the diastase test the correct diagnosis was usually made at operation or autopsy. In a series of 121 cases analyzed by Brocq,² the diagnosis of acute pancreatic necrosis was made in only 21. It was most commonly mistaken for perforation of a peptic ulcer (25 cases),

for ileus (23 cases), for peritonitis (15 cases), for appendicitis (13 cases) and for cholecystitis (11 cases). One physician mistook the case we have discussed for a rupture of the gall bladder. All the others of the staff made the correct diagnosis at their first examination. If, as stated, the symptoms of acute pancreatic necrosis are characteristic, it is a fair question to ask, Why is the diagnosis usually missed? The chief reason is that owing to its rarity it is not considered. Undoubtedly mild cases are often overlooked, and typical severe cases are certainly rare. Halsted, the distinguished Johns Hopkins surgeon, told Brown⁸ that he was eager to make a preoperative diagnosis of acute pancreatitis before he died, but his wish was not gratified. He saw only 2 cases, in neither was pancreatic disease suspected, and in both the correct diagnosis was determined only by exploratory operation. Körte⁹ said that surgeons fail to recognize the disease because they forget that every sick man has a pancreas. Garrod¹⁰ expressed the same thought when he wrote "The chief difficulty in diagnosing disease of the pancreas is in thinking of the pancreas."

Knowledge of etiologic factors should be an aid in diagnosis. The disease affects men and women about equally. There were 182 men and 150 women in Brocq's series. In the largest collection of cases assembled (Schmieden and Sebening⁸) 77 per cent of the patients were women. Most cases occur between the thirty fifth and fifty fifth years. The frequent association with biliary disease is undoubted. In some German clinics this is as high as 90 per cent. The percentage is much lower in some studies. Myers and Keefer⁹ found only 10 cases of biliary disease among 48 cases of acute pancreatic necrosis collected from the records of the Mallory Institute of Pathology at the Boston City Hospital. Jones¹ found that 22 cases of acute pancreatic necrosis at the Massachusetts General Hospital occurred in patients without gallstones. In a review of 38 cases of acute pancreatic necrosis that came to autopsy at the New Haven Hospital (Weiner and Tennant¹⁰) there was extra hepatic disease in only 6, or 16 per cent. In 25 cases (66 per cent) alcoholism was an associated factor.

PATHOLOGY

Twenty years ago I¹¹ wrote in the section on diseases of the pancreas in *Oxford Medicine*

The severe, acute disease of the pancreas often called acute hemorrhagic pancreatitis is unlike that of any other organ because the disease is due to the destructive action of the pancreatic juice on the very tissue that formed it and the general symptoms that occur

result from the absorption of toxic bodies produced by this autodigestion.

Opie and Meakins¹² in 1909 used the term acute hemorrhagic necrosis, but acute pancreatic necrosis (Guleke¹³) or acute toxic necrosis of the pancreas seems preferable, as the lesion is not always hemorrhagic. Brocq³ calls it *pancréatite aigue aseptique*—a good term because it emphasizes the non-bacterial nature of the disease. As early as 1909 Opie and Meakins pointed out the essential fact that the disease is not an infection but an intoxication. This truth has gained acceptance slowly, and some surgeons even today still falsely call the disease an infection. Nordmann¹⁴ emphasizes the importance of a knowledge of the pathology of the disease as a basis for correct ideas in regard to treatment. He says that so long as one speaks of pancreatitis and continues to regard the disease as one of inflammatory origin, and plans surgical procedures according to this conception, so long will he travel a false path. Autodigestion of the pancreas through activation of the pancreatic juice is the cause of the edema, necrosis and hemorrhages in the gland. Producing occlusion of the pancreatic ducts in dogs by ligatures applied with every aseptic precaution is followed by the speedy production of acute pancreatic necrosis in a large percentage of cases. This I know, since I have lost quite a number of dogs when the pancreatic ducts were tied for this purpose. These experiments disprove the theory that the introduction of infected material into the pancreatic ducts from the common bile duct is essential to the production of the disease, and they prove conclusively that trypsin can be formed readily within the gland from the inactive trypsinogen.

How the disease arises clinically remains a mystery. Many factors are probably concerned. The pancreatic duct is rarely found to be stained with bile at autopsy. Furthermore, the pressure in the duct is higher than that in the common duct during digestion, and pancreatic ferments have been recovered from the gall bladder in a considerable proportion of the cases examined. The common-channel theory of Opie explains very few cases. Many years ago Archibald¹⁵ suggested that spasm of the sphincter of Oddi might lead to the entrance of bile into the pancreatic duct, with the resulting development of acute pancreatic necrosis, and supported his theory by experimental evidence. Wangensteen and his associates¹⁶ have shown that by closing the sphincter of Oddi in cats by a ligature the stimulus furnished to the contractile mechanism of the gall bladder by a fat meal produced acute pancreatic necrosis in 15

out of 31 experiments. Only 2 of Weiner and Tennant's¹⁰ 38 cases could be explained on the basis of the reflux theory. In 3 other cases in which they found a common channel the pancreas was normal. Inasmuch as the ferments may be activated within the gland, as we have shown experimentally, the theory of Rich and Duff¹¹ that the disease is due to occlusion of the smaller pancreatic ducts by a metaplasia of the duct epithelium is an attractive one. However, in a great majority of cases the pancreas, the seat of acute pancreatic necrosis, fails to show this metaplasia with the resulting occlusion. Nervous and circulatory changes in the pancreas may prove to be most important in the etiology of this disease, but it is futile to speculate concerning them.

CLASSIFICATION OF CASES

The cases of acute pancreatic disease can be divided into three groups: acute pancreatic edema, acute pancreatic necrosis and suppurative pancreatitis. These will now be discussed.

Acute Pancreatic Edema

Since Zoepffel's¹⁸ paper in 1922 this disease has been recognized with increasing frequency. It is probably the commonest form of pancreatic disease, and is often associated with cholelithiasis. In this country excellent studies of this condition have been made by Elman¹⁹ and Cole.²⁰ The latter observed no less than 6 such cases in a series of 8 proved cases of acute pancreatic disease at the Illinois Research and Educational Hospital during a period of eighteen months. The symptoms are similar but of less intensity than those in acute pancreatic necrosis. Shock, according to Cole, is never encountered in this type of the disease. Acute pancreatic edema is frequently seen in association with gall-bladder disease, and the pain and vomiting are usually attributed to the accompanying cholelithiasis. There is a leukocytosis, but it is usually less than that in pancreatic necrosis. A high diastase value in the blood or urine is diagnostic of pancreatic involvement. Swelling and induration of the pancreas may be marked, and may involve either a portion or the whole of the gland. The condition is regarded as the earliest stage of acute pancreatic necrosis, but biopsies reveal only an interstitial edema. There is rarely any free fluid in the peritoneal cavity. There may be fat necrosis as in 2 of Zoepffel's original cases, but if there are areas of necrosis in the gland the condition has passed into the second stage and should be classed as mild acute pancreatic necrosis. Recovery as a rule occurs in a few days.

Acute Pancreatic Necrosis

This has already been described in sufficient detail. The case presented is typical of the disease in its severe form. Some patients die within a few hours, and at autopsy the pancreas may be converted into a hemorrhagic mass. These deaths were formerly attributed to apoplexy of the pancreas. A considerable number of cases were reported with this diagnosis before Fitz²¹ published his epoch-making lectures on acute pancreatitis in 1889. They were really fulminating cases of acute pancreatic necrosis in which the areas of necrosis were overlooked.

Suppurative Pancreatitis

To this group belong also the cases of true gangrene of the pancreas. Both conditions may occur secondary to acute pancreatic necrosis if bacteria lodge and grow in the necrotic tissue. They are rare sequelae. After initial improvement in a case of acute pancreatic necrosis the temperature increases and may be septic in type. The leukocytosis becomes more marked or develops for a second time and usually to a higher degree, the white-cell count sometimes reaching 30,000 or more. Pain and tenderness become localized, usually in the epigastrium or left loin. The physician should be alert to recognize this condition, as incision and drainage constitute the only treatment that will result in cure. If operation is delayed, general sepsis may occur. Suppurative pancreatitis with abscess formation is sometimes seen following the extension of a peptic ulcer into the pancreas, but this is rare. Bernhard²² says that in a series of 200 cases of acute pancreatic disease he saw only 1 of bacterial infection.

LABORATORY AIDS TO DIAGNOSIS

Increased Diastase Values

The most important laboratory aid in the diagnosis of acute pancreatic disease is the determination of the diastase activity of the urine and blood. The test has been applied now in hundreds of cases, and its value in the diagnosis of acute interstitial edema of the pancreas and of acute pancreatic necrosis is undoubted. The method introduced by Wohlgemuth²³ in 1908 and modified by him²⁴ in 1929 is the one most satisfactory for clinical use, because it is so simple that it can be carried out by any intern or laboratory technician. A report can be rendered within an hour of the receipt of the specimen, so that the test may be utilized as an aid in the speedy diagnosis of acute abdominal conditions. More accurate methods of amylase determination are available, but they

are time-consuming and require more equipment and the services of a chemist. As only a great increase in amylase values is of diagnostic significance, the Wohlgemuth method is entirely satisfactory for the purpose.

In 1918 McClure and I⁶ reported 4 cases of acute pancreatic necrosis in which all the diastase values in the urine were normal. We concluded at that time from our own experience and a study of 6 cases previously reported in the literature that the test was of very little value. The cause of our negative results is now clear. All the tests were performed relatively late in the course of the disease, one week or more after the diagnosis was made at operation. About ten years ago the important discovery was made that the diastase value usually falls to normal after the first two or three days. It may be elevated for only the first twenty-four hours. A fresh morning specimen of urine or the twenty-four hour amount should be used for the test. If there is a delay in making the examination the urine should be covered with a layer of toluol. Blood should be collected in a dry test tube and allowed to clot. The serum is used for the test. If diastase determinations of the urine are made daily or every other day valuable information is often obtained. The diastase activity of the urine should be at least 256 units to be of diagnostic value. If it is above this level it is a definite indication of pancreatic disease.

In the case we are studying the urine contained 256 units. Some authorities hold that this is not a sufficiently high value to incriminate the pancreas. It is regarded by all as the lower border of significant value. But note that in the case here reported the examination was not made until at least thirty-six hours after the onset. Fortunately subsequent determinations were made which are most instructive. The following day, the diastase value was at the normal level, only 64 units being present. The course of the curve in the chart certainly suggests that if a diastase determination had been made when the patient was admitted it would have been at a higher level. The rapid fall in diastase furnishes as strong evidence as did the original level of 256 units that the patient had acute pancreatic necrosis. The diastase test is said to be negative even in the first twenty-four hours of the disease in from 10 to 20 per cent of cases. According to Doberer,²⁶ examination of the urine is preferable to that of the blood. In the cases he studied in Clairmont's clinic the blood diastase was normal in the majority of cases, although urinary diastase was almost always increased. Hence other tests are necessary in some cases.

Increase of Lipase in the Blood

In 1932, Cherry and Crandall⁷ demonstrated that a lipase which hydrolyzes olive oil normally not present, appeared in the blood following the ligation of the pancreatic ducts of dogs. The activity of the enzyme, esterase, normally present in the blood as measured by hydrolysis of ethyl butyrate or tributyrin, did not show uniform increase in their experiments. They devised a simple titration method for the determination of lipase in the blood serum, using olive oil as a substrate. Comfort,⁸ using this method, recently obtained elevated values in 20 of 21 cases of acute pancreatic necrosis examined within ten days after the onset of symptoms. The upper limit of lipase activity in persons without pancreatic disease is given by him as about 1.5 cc in terms of N/20 sodium hydroxide per cubic centimeter of serum, although Cherry and Crandall found that the serums of 40 of 46 patients did not reveal any trace of lipase capable of splitting olive oil. In acute pancreatic necrosis a value as high as 10.2 cc. has been obtained. The earlier in the disease the blood was examined, the higher was the value. Fourteen days or more after onset the serum lipase was normal.

Leukocytosis

There is usually a marked increase in the leukocyte count which often exceeds 25,000. It is sometimes as high as 50,000. In a case of acute pancreatic edema in my series, proved by operation, the leukocyte count was 27,000, although the temperature was only 98.6°F. In the present case the leukocytes on admission numbered 18,400. A rapid fall, as occurred during the first week, is a good prognostic sign.

Hyperglycemia

The fasting blood sugar is elevated in 50 per cent or more of cases, hence its importance in diagnosis should be stressed. Brocq and Varangot⁹ found the blood sugar above 150 mg per 100 cc in 57 out of 72 cases and in 34 of these it was above 200 mg. Recently Dunlop and Hunt¹⁰ report that it was elevated in 6 out of 7 cases they studied, and in 5 of these to more than 200 mg. Even when the fasting level is normal a glucose tolerance test may prove of value. Löffler²¹ using Staub's method, demonstrated the value of this procedure. In 5 cases of acute pancreatic necrosis the initial blood sugar was below 140 mg and in 3 of these 110 mg or less. Yet in all 5 cases an abnormal glucose-tolerance test was obtained. In 2 of these the blood sugar level rose above 200 mg in the second or third hour.

Other Aids to Diagnosis

Some writers hold that an increase of urobilinogen is of diagnostic value. Bernhard³² found it increased in 11 out of 12 cases of acute pancreatic necrosis. In the present case there was a progressive rise during the first week, although it was absent at the first examination. Bile in the urine at onset was an aid in the diagnosis. A high serum bilirubin has been observed in some cases. The nonprotein nitrogen may be increased. It was above 40 mg per cent in 14 out of 25 cases studied by Bernhard³². An x-ray film of the abdomen and lower chest may be of diagnostic value. Berg³³ maintains that meteorism of the stomach and transverse colon occurs with great regularity in acute pancreatic necrosis, as well as changes in the lower part of the duodenum. Shadows at the bases of the lungs may be due to pancreatic disease, as Röppa³⁴ has shown.

TREATMENT

The case described in this lecture was one of fulminating acute pancreatic necrosis. Many surgeons would have held that an operation offered the only hope of recovery. Drs. Walker and Nowak thought differently. They did not operate, yet the patient recovered. At the beginning of 1929 all surgical authorities were agreed that early operation was indicated, although early diagnosis and early operation had failed to reduce the high mortality, which remained between 50 and 60 per cent. In that year Pólya³⁵ offered the first protest against this procedure. In 1938 Nordmann,¹⁴ in an excellent paper on the diagnosis and treatment of acute pancreatic necrosis, stated that the death rate among his patients had fallen from 50 to 24 per cent since conservative treatment had been followed. He gave other figures as follows: conservative treatment in Walzel's clinic resulted in a fall in death rate from 86 to 28 per cent, Bernhard's death rate fell to 7 per cent, Demel's fell from 78 to 28 per cent, and Haberer's from 54 to 23 per cent. In a discussion that followed the reading of Nordmann's paper all the surgeons present supported his views. Guleke,³⁶ the well-known authority on pancreatic disease, stated that of his 46 patients on whom operation was performed 12 died, a mortality of 26 per cent, while of 8 conservatively treated patients all recovered. Puhl³⁷ reported that under conservative treatment in the Kiel clinic the mortality fell from 45 to 7 per cent.

Some American statistics likewise show a lower mortality under conservative treatment. The experience at the Boston City Hospital is instructive. There the mortality rate has fallen from 54 per cent in cases submitted to early operation to 25

per cent under conservative measures (Lium³⁸). Dr. Walker³⁰ stated his views in a recent discussion as follows:

One can be sure that most edematous cases of pancreatitis, and some hemorrhagic ones, will recover spontaneously or by medical treatment. Practically it appears that if one suspects acute pancreatitis of low grade, as evidenced by symptoms and clinical findings, surgery is not advisable for the disease per se, but may be indicated on the basis of an accompanying acute lesion of the gall bladder. Likewise, emergency surgery is contraindicated in those cases of hemorrhagic pancreatitis where shock and toxemia are manifest. Under treatment consisting of parenteral fluids and decompression of the upper intestinal tract by the Wangensteen method, some of these cases will recover without surgery, and those in which surgery becomes necessary will be better prepared for it. The treatment of suppurative pancreatitis calls for no special comment, other than that the pancreas should be drained when pus is apparent.

The statistics just cited are additional evidence of the correctness of Dr. Walker's opinion that conservative treatment rather than operative procedures is indicated in dealing with acute pancreatic necrosis. With this view I am in accord. As the disease is not an infection but an intoxication in which trypsin and split-protein products are absorbed by the lymphatics and blood vessels of the pancreas, it would seem evident that this absorption cannot be prevented by any operation, but might on the other hand be increased by incising or even manipulating the pancreas.

COMPARATIVE STUDY OF THE TUBERCULIN PATCH TEST AND THE STANDARD INTRADERMAL TEST (PURIFIED PROTEIN DERIVATIVE)

ROBERT B. KERR, M.D.,* AND ABBOTT L. WINOGRAD, M.D.†

MANCHESTER AND NASHUA, NEW HAMPSHIRE

FOLLOWING the introduction of the tuberculin patch test by Vollmer and Goldberger¹ an attempt has been made to compare its value with the standard intradermal test used for several years by the New Hampshire Tuberculosis Association in its case finding surveys. These surveys have consisted in the tuberculin testing of various groups of high-school students throughout the State, followed by an x-ray examination of the lungs of all the positive reactors. The standard intradermal test consists of 0.1 cc. first strength Purified Protein Derivative, which corresponds to 0.1 cc. of a standard Old Tuberculin in the dilution of 1:10,000.

During 1938 we directed these case finding surveys, and the tuberculin patch test was compared with the standard intradermal test in 1455 high school pupils. Most of them were between twelve and sixteen years of age and hence in an age group that was deemed satisfactory for comparative testing. Both tests were made simultaneously on each child—the standard test intradermal on the left forearm and the patch test on the right forearm. Before applying the patch test the skin was cleansed with ether or acetone. In order to obtain their fullest co-operation, the pupils were enlightened in detail at the first session as to the purpose of the tests and the conditions necessary for the most effective results.

The following rules were to be observed

The patch-test area was to be kept absolutely dry.

If any portion of the adhesive became loosened it was to be immediately covered by a fresh piece, as perfect contact between the skin and the patch was desired.

The patch was not to be removed, even temporarily by the subject for any reason without consent of the nurse.

The patch was to be removed by the nurse at the end of forty-eight hours; the test was to be read at that time, and again after another forty-eight hours.

Any reaction at the site of the patch test within one week after the second reading was to be reported.

The majority of the pupils showed a very helpful

tests were sharply defined. Slight blistering was observed in the more pronounced reactions. It was noteworthy that in a few cases the patch test did not become positive until from five to seven days after the removal of the patch.

In practically all cases the patch-test results ran parallel with those of the intracutaneous test. The poor ones noted in the groups at Claremont and Pittsfield emphasize the importance of mechanical difficulties. Here alcohol was used in cleansing the arm in some instances, and a check-up showed that in nearly every case the adhesive had not stuck properly.

Judging from the results obtained, the patch test would seem to lend itself to large-scale group testing for the following reasons: reliability (it compares favorably with the standard intradermal test), ease of application (it may be applied rapidly even by an unskilled person, and there are no instruments to sterilize), acceptability (the fear of the needle in the minds of both the parents and the child is no small force in holding back a campaign for the skin-testing of large groups), and stability over long periods (since the tuberculin on the patches is in dry form, they may be kept indefinitely). Against the use of the patch test are the obvious mechanical difficulties which are intrinsic in the patch itself or due to lack of co-operation on the part of the subject. The former can be helped by an improvement in the quality of the adhesive plaster used, whereas education as to the value of the test will help to ensure the co-operation and interest of the child.

The patch test offers to the internist and pedi-

atrician a simple, effective and acceptable means for the tuberculin testing of private patients. This fact and the adaptability of the method to group testing should give impetus to the worthy cam-

TABLE 2 *Results of X-Ray Examination of Positive Reactors*

| RESULTS | NO OF CASES |

paign, the eventual goal of which is the tuberculin testing of all citizens of the United States.

It is interesting to note that 187 of the positive reactors received a follow-up x-ray examination of the lungs with the results shown in Table 2.

SUMMARY AND CONCLUSIONS

An attempt has been made to evaluate the use of the tuberculin patch test in comparison with that of the standard intradermal test now used in New Hampshire in tuberculosis case-finding surveys. The results tend to show that the patch test, because of its reliability, ease of application, general acceptability and stability, is equally satisfactory and should prove to be a useful method for case finding, not only in the testing of large groups but also in private practice.

CAN INFANTILE PARALYSIS BE SPREAD BY BATHING IN SEWAGE POLLUTED WATERS?

SAMUEL M. ELLSWORTH*

BOSTON

INFANTILE paralysis, otherwise known as acute anterior poliomyelitis, has appeared in epidemic form in the United States at more or less regular intervals during the last thirty years. While epidemics were reported in Europe previous to 1907, this date marks the first serious one in the United States. Because of the nature of the disease and the effect on its victims, great interest has been aroused in its mode of transmission and the methods of controlling its spread.

Epidemiologists agree that infantile paralysis is commonly transmitted by direct contact. There also seems to be evidence that it is sometimes transmitted indirectly through a third person. It is held by some that contact infection is not the only way by which the disease is transmitted. Ever since the outbreak in 1907, each epidemic has suggested new possibilities as to agencies of transmission. Practically every conceivable agent which might carry the disease has been investigated during the last thirty years, but so far the chief value of these investigations has been only to disprove this or that theory.

In 1934 I was engaged to study the problem of sewage disposal at Fall River, Massachusetts. The sewage of that city is discharged without treatment through a number of outfall sewers into the waters of Mount Hope Bay, at the mouth of the Taunton River. During the course of the investigation it was necessary to study the tidal currents in this bay, partly to determine the effect of the discharge of sewage along the waterfront, and partly to aid in selecting a suitable location for an outfall sewer from a proposed sewage treatment plant.

For the most part the waterfront at Fall River is devoted to commercial and industrial uses. At several points along it however there are beaches, two of which are used quite extensively for bathing. While the latter are at some distance from the most important outfall sewers, current observations showed that under certain conditions of wind and tide they were affected by sewage pollution. Many years ago sewage pollution in Mount Hope Bay became so serious that the taking of shellfish was restricted by the state health authorities, and, partly as a result of the Fall River

sewerage investigation in 1934, the restricted area was extended well beyond the former limits.

In the summer of 1935 Massachusetts was visited by an epidemic of infantile paralysis, the incidence of which, according to the Massachusetts Department of Public Health reached the third highest figure in the history of the State. Fall River, with 114 cases reported, had the highest incidence of any city or town. Having but recently observed the effect of sewage upon the bathing beaches at Fall River, I could not but wonder whether this pollution had any effect on the high incidence of infantile paralysis in that city. It has been shown experimentally that the virus of infantile paralysis can gain entrance into the central nervous system through the olfactory nerve endings, and there is considerable evidence that this avenue of infection through the nasal mucosa, is quite common. If it were possible for sewage to carry a sufficient concentration of this virus, what better way would there be of producing a case of infantile paralysis than frequent flushing of the nasal passages with sewage-polluted water, as would be done in bathing, particularly by youngsters with a natural proclivity for diving and swimming under water?

This possibility was also suggested by the fact that the points of highest incidence in Massachusetts in 1935 seemed to be in communities bordering on waters used for bathing and affected by sewage pollution. A large number of cases were reported in the Boston Metropolitan District and in the communities bordering on Salem and Beverly harbors. In each of these districts there are many bathing beaches some of which are known to be affected by sewage pollution. The cities and towns along the Merrimac River reported a high incidence of infantile paralysis in 1935. Sewage pollution along that river has for many years been a serious problem, although bathing in its polluted stretches is not common. The highest concentration of pollution occurs near Haverhill. In this connection a statement in the annual report of the Massachusetts Department of Public Health for 1917 appears to have some significance. In the section of the report concerning acute poliomyelitis in that year the following comment was made: Cases were well distributed except in Haverhill where 38 cases were reported.

*Lecturer on sanitary engineering design, Harvard Graduate School of Engineering; consulting sanitary engineer.

from June to September. The disease has prevailed constantly in Haverhill for the past few years to a greater extent than in some other communities of the same size or larger."

Previous to 1912 it had been demonstrated that the virus of infantile paralysis could be recovered from the mucosa of the intestinal tract and from the feces.¹ Trask, Vignec and Paul² have recently reported on the recovery of the virus from the stools of an infant following an illness from abortive poliomyelitis. Emulsions prepared from the stools on the second, fourteenth and twenty-fifth days following the onset of the disease were used to inoculate monkeys. In each case paralysis developed seven days after inoculation. As evidence of the resistance of the virus, one of the stool samples was kept under refrigeration for ten weeks and the virus remained viable for this length of time. According to the authors, such facts suggest that, during an epidemic, unrecognized forms of the disease may be responsible for a high degree of pollution of sewage with poliomyelitis virus.

Lovett and Richardson³ as far back as 1911 suggested that the disease seemed to prefer river valleys, but concluded that this was probably because of the increased opportunities for personal contact, since highways and railroads frequently follow such valleys. They reported, however, that of 419 cases from 1908 to 1910, 105 cases, or slightly more than 25 per cent, showed a history of swimming, wading or paddling in more or less contaminated water just prior to the attack. However, these authors called attention to 457 cases during the same period, 34 per cent of which showed a history of having been preceded by accidents, overexertion or falls, and concluded that there was at least as much significance in the effect of accidents as in the effect of bathing in contaminated water. If the cases studied by Lovett and Richardson followed the usual age distribution, it is obvious that a relatively large number of children in the first-mentioned 419 cases would have been too young either to bathe or to paddle. Excluding the very young children, the proportion of cases showing a history of bathing in contaminated water would have been substantially greater than 25 per cent. With the evidence gathered by Lovett and Richardson it may seem strange that they gave this factor so little weight, it should be remembered, however, that little was known regarding the disease in 1911 as compared with what is known today. The following statement in their treatise is significant: "There is nothing in the pathologic anatomy and histology of the disease which shows the mode of entrance of the infectious agent into the body nor whether it

reaches the central nervous system by the blood or by the lymph stream."

It is generally held that infection by poliomyelitis is much more widespread than would be indicated by the number of cases diagnosed or identified as such. Children as well as adults may have the disease without having recognizable symptoms. If some of these subjects carry the virus in the intestinal tract for several weeks, which according to the findings of Trask, Vignec and Paul² is possible, the virus must be present in relatively large concentrations in sewage during severe epidemics.

Epidemiologists in their studies of this disease have considered and investigated the possibility of indirect transmission by drinking water, food, rats, insects, birds, domestic animals and air-borne dust particles. While general sanitary conditions in areas affected by the disease have been noted, it would seem that insufficient study has been given to the possibility of infection through bathing in sewage-polluted water.

It is my conviction that there is sufficient presumptive evidence to warrant further investigation and research. The argument may be stated briefly as follows:

Since epidemic infantile paralysis occurs almost invariably during the summer, it is reasonable to assume that the disease may be spread not only by direct or indirect personal contact, but also by some agency which is effective during the warm summer months.

From the evidence in Massachusetts, the incidence of the disease during epidemics is generally highest in communities situated along the seacoast or along rivers the waters of which are subject to sewage pollution.

It has been possible to produce the disease in monkeys from the virus obtained from human stools of a case of abortive poliomyelitis as long as twenty-five days after the onset of the disease. It has also been shown that the virus in refrigerated human stools remains viable for at least ten weeks.

For every recognized case there are apparently many unrecognized cases by which infection may be spread, such cases never having shown any clinical evidence of the disease.

During epidemics, and probably at other times, the virus from active cases or from carriers is undoubtedly present in the sewage of an affected community.

Infection by way of the olfactory nerves is possible, and it appears probable that this is a common way of contracting the disease.

Given a sufficient concentration of the virus in sewage-polluted water, it is conceivable that infection can be caused by the admission of such water into the nasal passages of a bather.

While the possibility of infection by bathing in sewage polluted water has been considered in the past and tentatively dismissed for lack of evidence, sufficient additional knowledge has been accumulated in recent years concerning infantile paralysis to warrant reconsideration of the conclusions reached by previous investigators. It is probably impossible to obtain much help from a study of the records of past epidemics. Epidemiological studies in the past have generally made no special attempt to connect the spread of infantile paralysis to bathing in sewage polluted water. In any future epidemic it would seem advisable that more attention be given to this possibility than has been given in the past. In the meantime some further enlightenment might well be obtained through laboratory research directed toward this specific objective.

It is realized that this theory of transmission of infection has obvious weaknesses. Even though infection can be traced to a bathing-place, is it not possible that contact infection at such places is as instrumental in spreading the disease as is infection by the virus contained in polluted sewage? Can it be that the virus is present in sewage polluted waters in sufficient concentration, even during an epidemic, to cause infection by simply being flushed through the nasal passages? These and similar questions cannot yet be answered. Here is a disease with a seasonal prevalence corresponding to the usual bathing season. In its seasonal prevalence it is more like a disease of intestinal origin than one spread by contact through drop let infection, such as measles, mumps, whoop-

ing cough and similar diseases which commonly occur during cold weather. Numerous attempts have been made to connect the incidence of the disease with some agent or condition which is effective during the summer season. Until the reason for this seasonal occurrence has been discovered, any rational theory of transmission that has not been definitely disproved deserves consideration and study. It is hoped that this brief discussion may suggest appropriate research both in the laboratory and in the field when the next epidemic occurs.

Recent investigations during the summer of 1939 have been reported by Paul Trask and Culotta. At the International Congress of Microbiology Paul⁴ described studies made by him and his associates at Charleston, South Carolina and Detroit, Michigan, on the successful recovery of the virus of poliomyelitis from sewage. A brief report of the work at Charleston has been published by these authors⁵ who conclude: "It is not evident from this work whether the presence of poliomyelitis virus in sewage is a direct or even an indirect link in the chain which leads this infectious agent from one patient to another in this disease. Our report merely calls attention to the fact that poliomyelitis virus may not only be present in urban sewage but also that it may be present in appreciable quantities."

Another recent discovery which may have a bearing on the theory of spread of infection by bathing is reported by Howe and Bodian.⁶ They describe the infection of monkeys following the dropping of the virus of poliomyelitis into the conjunctival sac.

ALLERGY TO TUBERCLE BACILLI AS A POSSIBLE CAUSE OF ACUTE PULMONIC CONSOLIDATION

D ALAN SAMPSON, MD*

PHILADELPHIA

TUBERCULOUS lobar pneumonia is ordinarily thought of as a form of the disease in which the onset is sudden, with consolidation over an area similar in extent to that seen in pneumococcal lobar pneumonia. In the tuberculous form, instead of the consolidated area's resolving as in the pneumococcal disease, the consolidation usually goes on to caseation, the caseous tissue breaks down to form cavities and the course of the disease is rapidly and progressively downhill, death occurring within about six weeks.¹

The case reported herewith is unusual in that while it simulated ordinary lobar pneumonia in most of its clinical features, the presence of tubercle bacilli in the sputum caused a diagnosis of tuberculous lobar pneumonia to be made, yet caseation did not occur and the patient recovered.

CASE REPORT

S U (No U42829), a 28 year old, white married woman, entered the Massachusetts General Hospital on April 27, 1937, complaining of a "cold" which had been present for 1 week. In the past she had had frequent "colds" and for the preceding two winters they had been almost continuous, but they usually consisted only of fullness in the head, with slight nonproductive cough and occasional soreness of the throat. For 3 months before the onset of the present illness the patient had been well. One week before coming to the hospital she had noticed an aching pain in the chest, localized rather vaguely about the upper part of the sternum. Associated with this were a raw sore throat, hoarseness, malaise and chilly sensations. Two days later she began to have a hacking, nonproductive cough, the sore throat subsided but the ache extended to most of the muscles and joints, being most marked diffusely over the chest and about the neck and shoulders. On the night before entry, after going to bed she had a drenching sweat lasting 1 hour and followed by a severe chill lasting 2 hours. There had been no previous occurrence of sweats or chills, no hemoptysis, no weight loss and no known exposure to tuberculosis. The past history was otherwise irrelevant, and the family history was negative.

Physical examination showed a pale, listless young woman. The throat was slightly red, the tonsils had been removed, no enlarged lymph nodes were present. Dullness on percussion was present at the right apex and in the right infraclavicular region, and was associated with an increase in the intensity of the breath sounds, fine rales and egophony, the signs were interpreted as indicating consolidation in the right upper lobe. The physical examination was otherwise negative.

A roentgenogram of the chest on admission showed a

homogeneous area of opacity involving the greater part of the right upper lobe, the lungs were clear elsewhere except for a few calcified nodes at the left hilum. The appearance was that of consolidation consistent with lobar pneumonia.

An attempt was made to type the sputum. This, however, was rather unsatisfactory because practically no sputum could be obtained. The Neufeld method gave negative results for Types 1, 2 and 4. The white cell count was 5700 with 70 per cent polymorphonuclears, 12 per cent large lymphocytes, 8 per cent small lymphocytes and 10 per cent mononuclears. The urine was essentially normal. During the 1st hospital day the temperature rose from 101 to 104°F, the pulse from 90 to 110, and the respirations from 20 to 24. On the 2nd day the temperature, pulse and respirations remained unchanged, and the white-cell count was 7500. Sputum however was more plentiful, about 30 cc. being raised, and numerous acid fast bacilli characteristic of tubercle bacilli were seen in the stained smear. This fact was confirmed by several observers with different preparations of the sputum. On the 4th day, while the temperature, pulse and respirations were unchanged, there was only a trace of sputum and the bacilli were as frequent, only one bacillus was present per five fields. Subsequent progress was satisfactory. The temperature returned to normal by lysis on the 6th and 7th days, with a corresponding drop in the pulse and respirations. No further sputum could be obtained for study, further white-cell counts did not exceed 6000, and the patient's general condition rapidly improved. A few hours before discharge on the 9th hospital day a roentgenogram showed almost complete resolution of the area of consolidation, there remained only a small area of decreased radiance along the right upper border of the mediastinum.

The patient spent the next 2 months at a tuberculosis sanatorium, where her condition was at all times perfectly satisfactory. All roentgenographic examinations made there were negative. A third film of the chest taken at the Massachusetts General Hospital on July 21, 1937, showed no trace of the area of consolidation. At this time the patient had gained 5 pounds in weight and was in excellent health. An x-ray film of the chest taken June 27, 1938, showed the appearance unchanged.

The association of positive sputums with a pulmonary consolidation which rapidly cleared raises the interesting questions: What was the nature of the consolidation, and what was the mechanism of its production?

The low leukocyte count, the failure to identify a causative pneumococcus and the return of the temperature to normal by lysis rather than by crisis show that this was not a case of typical lobar pneumonia. Without the discovery of the tubercle bacilli it might have been regarded as an atypical pneumonia. However, the presence of

*Formerly roentgenologist, Massachusetts General Hospital, Boston.

tubercle bacilli is not a matter to be lightly dismissed. It has been suggested that the best explanation of this and the other features of the case is that it was one of tuberculous lobar pneumonia, allergic in nature and non-caseating in its course.

The clinicopathological picture of acute caseous tuberculous pneumonia has been well summed up by Sante.² He points out that the consolidation, instead of clearing up rapidly as in the pneumococcal disease, persists and goes on to caseation and, as a rule, death. He mentions the possibility that the process is allergic in nature. In cases which Fränkel and Troye³ studied they observed the subsequent occurrence of caseation in the area of consolidation and, if the patient lived long enough, cavity formation. It is not generally realized, however, that tuberculous pneumonia may instead be non-caseating. The reason that this is not well known, of course, is the much greater frequency with which caseation instead of resolution occurs as the rule. In fact, one's first thought would be that a tuberculous process of the size present in this case would not clear in a little over a week. Nevertheless, as Wessler and Jaches⁴ have pointed out, the clinical course of tuberculous pneumonia offers many surprises. They state that while the disease is as a rule ultimately, if not immediately, fatal, extensive areas of consolidation may at times resorb rapidly without the development of caseation, and that even in cases in which caseation and cavitation have occurred, recovery may sometimes take place with disappearance of the infiltration and cavities. The virulence of the toxin they consider to be the factor determining the course of events. Their discussion⁵ of the subject is so complete and excellent that it should be read.

Wessler and Jaches attributed the onset of tuberculous pneumonia to overflow from an apical cavity. Such an explanation, however, would hardly be applicable to the case herewith reported. How can we explain the production of tuberculous pneumonia in a patient who presumably has been free from parenchymal involvement up to the time of onset of the pneumonia? Floyd⁶ states that in thoracic tuberculous adenitis when, from caseation and softening, rupture of a lymph node into a bronchus occurs, the material may be expectorated with relief of symptoms or an inhalation tuberculous pneumonia may develop. Lord⁷ likewise attributes the confluent acute or lobar form of tuberculous pneumonia to aspiration of disintegrated tuberculous material from a cavity at the apex or from a caseous node, probably to be ascribed to the effects of the toxins of the tubercle

bacillus on allergic soil. Fränkel and Troye³ were unable as a rule to recover tubercle bacilli from the sputum of patients with tuberculous pneumonia, and considered that the process in its early stages might be regarded as similar to a local tuberculin reaction. Actual allergic reactions of a similar nature have been demonstrated by Fried⁸ in his experimental work with the pneumococcus; he expressed the view that the acute exudate occurring in the lung following the intratracheal injection of heterologous serum depended on a state of local pulmonary allergy. He affirmed the observations of Wadsworth⁹ that in animals partially or incompletely immunized against the pneumococcus a subsequent infection with highly virulent pneumococci injected intratracheally produced a lesion akin to human lobar pneumonia.

On this basis and in view of the sequence of events which occurred in the case herewith reported, it is proposed that the case was one of allergic non-caseating tuberculous lobar pneumonia. It seems reasonable to assume that this patient had been harboring an active tuberculous focus, possibly in the form of one or more infected lymph nodes, and that a state of partial immunization had been produced. One of these nodes may have gone on to caseation with aspiration of some of the infected material into the lung, and so produced an allergic response in the form of the consolidation in the right upper lobe. Of unusual interest is the fact that the process in the lung did not go on to caseation and cavity formation, but instead rapidly resolved, leaving a normal lung and thus simulated an ordinary lobar pneumonia. The rapid recovery may have been due to this patient's having developed a higher degree of immunity than that which had been present in the cases of Fränkel and Troye, in support of this hypothesis is the evidence of the presence of calcified nodes at the left hilum.

SUMMARY

A case is presented in which, although tubercle bacilli were present in the sputum, the clinical course and physical and roentgenological findings were those of an atypical lobar pneumonia of the right upper lobe. It is suggested that in this case a tuberculous lobar pneumonia was produced by the introduction of disintegrated tuberculous material into the lung of an individual who was in a state of partial immunity, and that the resultant consolidation was an allergic response comparable to a local tuberculin reaction. Such a process usually goes on to caseation, cavitation and death; in the case presented there was presumably a high degree of immunity so that rapid

and complete recovery occurred without demonstrable residuum

1930 Chestnut Street.

REPORT ON MEDICAL PROGRESS

MEDICAL ASPECTS OF OBSTETRICS

THOMAS R. GOETHALS, M.D.*

BOSTON

YEARLY progress in the medical aspects of obstetrics is marked by the accumulation of evidence supporting or refuting ideas, claims and theories previously advanced by workers in the field. The discoveries arising from physiological, chemical and biological investigations must be subjected to clinical tests before their general application to clinical problems can be evaluated, hence the work of Taylor and the Smiths must follow that of Zondek and Aschheim, and the work of Colebrook and Long that of Domagk.

The report of progress made last year failed to mention the association of syphilis and the pregnant state, an omission for which I wish to make amends at the present time. It has long been known that a history of syphilis may be difficult if not impossible to obtain, and that the diagnosis of a pre-existing or even of a coincident infection in the pregnant woman may escape the usual clinical examination. It is also a matter of record, from many sources, that prompt and efficient antisyphilitic treatment, especially if applied during the first half of pregnancy, will not only reduce the fetal wastage from miscarriage and intrauterine death practically to the vanishing point, but will also similarly reduce the incidence of congenital syphilis in the newborn infant. The recent reports of Halloran,¹ Hillis and Benensohn² and McCord³ are well worthy of study, as showing that the pregnant syphilitic woman who is promptly treated has at least a 93 per cent chance of bearing a healthy infant.

Since these facts are clear, the attention of the profession and of the public has been intensively directed to the advisability of routine serological examination of every gravida at the time of her first visit to the physician. Seventeen states,⁴ Massachusetts included as of November 1, 1939,

have more or less recently enacted laws requiring routine prenatal blood tests. It is confidently expected that this measure will reduce the incidence of congenital syphilis to a level far below that of the 78 cases reported in this state in 1937 and 1938.⁴

The problems presented by the association of pulmonary tuberculosis and pregnancy differ in considerable degree from those where syphilis is involved. In both conditions, however, early diagnosis of the pathologic state is of the greatest importance. Eisele and Mason⁵ report the discovery of unsuspected pulmonary tuberculosis by stereoscopic roentgenography in 106 per cent of 4040 patients attending the prenatal clinic of the Chicago Lying-In Hospital and routinely fluoroscoped. Since the incidence of unsuspected tuberculosis thus discovered was approximately the same as the incidence (0.87 per cent) of unsuspected syphilis discovered by routine Wassermann and Kahn tests carried out in the same clinic over the same period of time, these writers state that routine roentgenological examinations of the chest should rank with routine serological tests as a medical necessity in pregnant women. Jameson,⁶ however, in commenting upon a proposition that the New York State Department of Health study by x-ray every woman attending antepartum clinics, deprecates the idea on the grounds of the expense involved, even as a research problem, pointing out that the results of a study so conducted would fail to answer the question of the incidence of tuberculosis in pregnancy except as applied to the rather special low income group of patients who would be seen at the state-conducted clinics.

Jameson⁷ reports an investigation of the effects of pulmonary tuberculosis and pregnancy upon each other as observed at the Trudeau Sanatorium. He compares 363 tuberculous women patients be-

*Assistant professor of obstetrics, Harvard Medical School, assistant visiting obstetrician Boston Lying in Hospital, obstetrician Massachusetts General Hospital.

tween the ages of twenty five and thirty five inclusive, who had had no viable pregnancies within six months preceding the development of the disease, with 54 patients of the same age group whose onset of tuberculosis either dated from a pregnancy, developed during a pregnancy or developed within six months of the termination of a full term or viable gestation, and with 34 others who became pregnant while tuberculous. His conclusions indicate that about 12 per cent of the cases showed a possible relation between the onset of the disease and a preceding viable gestation, that symptoms appeared during pregnancy in 35 per cent of the cases and that 4.8 per cent dated from parturition. He found no significant difference in the death rate from tuberculosis in the patients in whom the onset of the disease was related to a full term or viable pregnancy, as compared with a group of nulliparas of the same age group who showed lesions of similar extent.

Both Jameson, and Seeley, Siddall and Balzer,⁷ the latter in a survey of 109 tuberculous gravidas, stress the importance of adequate prenatal treatment of the tuberculosis. Seeley and his co workers pay especial attention to collapse therapy in their article, stating that the results in their series were especially good when there had been treatment for the tuberculosis before pregnancy started, and also when pneumothorax had been instituted during the first trimester.

These findings indicate the trend of results among tuberculous women whose pregnancies are not artificially terminated because of the tuberculosis per se, and re-emphasize the conclusions of Floyd quoted in last year's review.

Pneumonia occurring in pregnancy returns a place of honor among the most dreaded complications. Finland and Dublin⁸ have analyzed a series of 212 cases of typed pneumococcal pneumonia complicating pregnancy and the puerperium, stating that the incidence of pneumococcal types in these cases was similar to that found in all cases of pneumonia in adults. The death rate for each decade was found to be higher for pneumonia complicating pregnancy and the puerperium than for pneumonia irrespective of the pregnant or puerperal state. The death rates were highest for late pregnancy and for women whose pregnancy was terminated during the disease. The mortality however, in serum treated patients was only 20 per cent, as compared with 35 per cent in corresponding non serum treated patients, and the authors, in analyzing the conditions contributing to the failure of serum therapy, predict that early and adequate treatment with the homologous type specific anti pneumococcus serums can be ex-

pected to reduce materially the high death rate from the pneumonias complicating pregnancy.

The foregoing makes encouraging reading, and it is to be hoped that sulfapyridine therapy will be of avail to lessen the mortality rate in pneumonias for which specific antisera are still undiscovered.

The use of sulfanilamide in puerperal and post abortal infections is reported by various authors. Gordon and Rosenthal¹⁰ state that the drug was used in large doses in 118 patients with severe puerperal infections regardless of etiology, with 38 per cent of the results prompt and satisfactory, 38 per cent unconvincing but encouraging, 20 per cent not beneficial and 4 per cent fatal. Morris¹¹ discusses a series of 204 puerperal and postabortal cases of infection, all cultured on admission, of which 97 were treated with sulfanilamide regardless of the organism involved. He found, as one would expect, that cases of infection limited to the uterus, vagina or perineum showed no mortality, that cases involving the pelvic cellular connective tissue, tubes, pelvic peritoneum or veins showed no puerperal mortality but a 12.5 per cent post abortal mortality in the control or untreated group, that 1 of the 2 patients with general peritonitis treated with sulfanilamide died, whereas all 3 patients in the control group died, that 3 patients with postpartum septicemia died whether or not sulfanilamide was used, and that post abortal septicemia showed a mortality of 60 per cent among 5 untreated women, while neither of 2 such patients treated with the drug died.

Much more enlightening are the articles by Chandler and Janeway¹² and by Sadash and Mahan¹³. The former give a complete summary of the use of sulfanilamide in puerperal infections, especially those caused by the hemolytic streptococcus. They discuss the classification of these organisms, the mechanism of invasion and the role played by them in puerperal infections. They call attention to the fact that the Group A strains, which with rare exceptions are always the culprits in human puerperal infection of streptococcal origin are normally present neither in the vagina before or after delivery in the absence of a definite infection, nor in the feces of normal pregnant women, and that puerperal septic infection is chiefly derived from the nasopharynx of contacts. They discuss in detail the method of treatment of streptococcal infections of pregnancy and the puerperium, and outline their recommendations, both for sulfanilamide treatment in the presence of a negative blood culture and for immunotransfusions in cases where the blood culture is positive, or where the clinical response to

sulfanilamide alone is unsatisfactory. Sadusk and Manahan report 2 cases of uterine infection with *Clostridium welchii*, both postabortal, one following packing of the uterus with dry gauze to terminate an early pregnancy, the other subsequent to an unsterile vaginal examination after the onset of bleeding. Both cases had positive blood cultures, but in each case the blood stream was rapidly sterilized and the patient recovered.

It seems to me that barrels of ink have been expended and tons of paper wasted in attempts to derive "results" in the treatment of puerperal infection where the bacteriology has been either unknown or, if known, has been disregarded. The pioneer work of Colebrook and his associates,¹⁴ Lyons,^{15, 16} Keefer¹⁷ and Long, Bliss and Finestone,¹⁸ to name but a few, has been based on knowledge and application of clinical bacteriology and immunology, those sciences the tardy application of which to puerperal infection is bringing forth such encouraging results. Although much remains to be learned, the advances of recent years are bringing us closer than ever before to a rational and effective understanding of the prophylaxis and therapy of puerperal infection.

Epilepsy associated with pregnancy has been discussed by Baptisti,¹⁹ who reports 37 cases of gestation complicated with idiopathic epilepsy. In 21 cases the evidence showed that pregnancy had no effect on the disease, in 5 the condition was improved during pregnancy, in 4 it was made worse, and in 4 it began with pregnancy, 3 cases were unclassifiable. Clinical characteristics of the convulsion per se do not serve to differentiate epilepsy and eclampsia, as the blood pressure may be elevated during an epileptic attack and the convulsion may be followed by albuminuria. The most valuable point is the history of previous seizures, but, as this study indicates, over 10 per cent of epileptic patients have their first convulsion during pregnancy.

The question of therapeutic abortion may be raised in the case of the pregnant epileptic. To do so in the interest of the mother would appear, from Baptisti's figures, to be unjustifiable in 70 per cent of cases. On the other hand, Haupt²⁰ and Hoffmann²¹ call attention to the danger of the occasional development of status epilepticus with its bad prognosis for the patient, and it may be necessary in the case where convulsions are much more frequent during pregnancy to consider abortion. To advise therapeutic interruption for the reason that the infant may inherit the disease is even more debatable. Baptisti quotes Lennox as reporting a heredity incidence of about

10 per cent. The recent work of Lennox, Gibbs and Gibbs,²² reporting the occurrence, by electroencephalographic tracings, of dysrhythmia in at least one parent of 94 per cent of patients with epilepsy, suggests a greater familial predisposition than had previously been suspected. It may be that such determinations will lead in the future to a better rationale for interrupting pregnancy in epileptic patients.

No report of progress in obstetrics would be complete without some reference to the problem of hypertension and albuminuria in pregnancy, commonly known as pre-eclamptic toxemia. Numerous articles appear each year in the literature dealing with the etiology, physiology, pathology, clinical course, classification, sequelae and treatment of this complex syndrome, a few of which will be discussed.

In the matter of etiology the superficial similarity of the toxemias of late pregnancy to essential hypertension on the one hand and to nephritis on the other are matters of common knowledge. Dieckmann, of Chicago, and Reid and Teel, of Boston, have made some progress in differentiating the primary hypertension group and the secondary nephritic or vascular renal group from the welter of so-called toxemics. Dieckmann and Brown²³ maintain that the term "toxemia of pregnancy" should be restricted to those abnormal conditions in pregnancy which are characterized by the occurrence of one or more of the following signs: hypertension, edema, albuminuria, convulsions. The group includes eclampsia, 44 per cent, pre-eclampsia, 47 per cent, vascular renal disease, 36 per cent, essential hypertension, 12 per cent, and acute glomerulonephritis, 05 per cent. Eclampsia and pre-eclampsia are distinct disease entities occurring only in pregnant women.

If these claims are substantiated, the immediate etiology of the toxemias will be found to lie primarily in essential hypertension in about half of all cases, and the ultimate causation in the factors which initiate the hypertensive state. Since Dieckmann believes that hypertension ultimately becomes vascular renal disease, the vast majority of nephritic syndromes, save only those based on glomerulonephritis and pyelonephritis, would appear to have had their inception in arterial disease.

This conclusion still leaves half the field to the conception of a pre-eclamptic-eclamptic syndrome, a theory which the obstetrician is loath to forsake. Peters²⁴ claims that little has been found to support the general impression that toxemias are manifestations of some abnormality of metabolism.

or of disco-ordination of endocrine function. Colvin and Bartholomew,³ on the other hand, claim that a low metabolic rate in early gestation predisposes to the eventual development of toxemia, stating that the blood cholesterol is increased above its normal level in such cases, causing vascular changes in the arteries both of the systemic circulation and of the placenta, and that at the onset of clinical toxemia the basal metabolic rate rises and the blood cholesterol level drops sharply. The development of toxemia they attribute to the trauma of fetal movements, causing rupture of placental vessels at the site of trauma and a resultant infarction, followed by the liberation of guanidine from the infarcted tissues. From the endocrine standpoint, Smith and Smith¹⁴ find excessive amounts of prolactin in the blood in 88 per cent of their toxemic and eclamptic patients, but no corresponding rise of this hormone in cases diagnosed as hypertension or nephritis. Rakoff¹⁷ substantiates this finding, in toxemic patients, but states that the findings were the same in 3 cases of nephritic toxemia. These authors are guarded in the matter of claiming any etiologic cause for toxemia in their observations, while Taylor and Scadron,¹ from similar surveys, conclude that the hormonal changes in toxemia may be simply the result of a disturbance of renal, hepatic or placental physiology.

Strauss¹⁸ is another observer who is skeptical of the existence of "toxemia of pregnancy," claiming that 85 per cent of patients so classified have primary vascular or renal disease. The remaining 15 per cent are due, he believes, to water retention resulting from low plasma proteins, excessive sodium intake or both. While there is no doubt that some cases of toxemia may be explained on this basis, Dieckmann and Brown²² deny that hypoproteinemia is a factor in causing toxemia.

Reid and Teel^{10, 11} have made two valuable contributions to the clinical course and follow up of the various groups of toxemic patients. Among 122 patients with known hypertension prior to and in the first trimester of pregnancy, 105 were carried through to viability; 70 per cent developed albuminuria, but none showed signs of renal insufficiency. 63 per cent suffered from an increase in hypertension during the last trimester. The fetal mortality in the 105 cases was 9.5 per cent. Five maternal deaths occurred in this group, 1 of postpartum amebic dysentery, 1 of eclampsia, the patient refusing adequate supervision and 3 later, of hypertension. The subsequent history of the mothers showed continuance and eventual increase in the hypertension in practically all cases, but a surprisingly small incidence of postpartum albuminuria.

The same authors report a group of 15 patients with known glomerulonephritis occurring one to sixteen years before pregnancy. All showed albuminuria of some degree, with varying numbers of red cells and casts in the sediment from the beginning of pregnancy. Blood pressures ranged from normal to 160 systolic, 110 diastolic. No therapeutic abortions were done. During pregnancy, blood pressure and albuminuria tended to increase moderately, but only 1 case showed sudden weight gain, development of edema and shifts in body water such as occur in simple pre-eclampsia. Fourteen patients delivered live viable babies. Subsequent histories have shown that 4 of the patients are substantially worse than before pregnancy.

Reporting 235 cases of Grade 1 (mild) pre-eclampsia in which the patients were known to have normal blood pressures and urines in early pregnancy, Reid and Teel found no maternal deaths. The fetal mortality was 4.8 per cent, all viable stillbirths. Subsequent histories of the patients showed no impairment of renal function, but 21 per cent had blood pressures of over 150 mm., three times the incidence of hypertension for women of similar age distribution irrespective of pregnancy. Fifty cases classed as Grade 2 (severe) pre-eclampsia yielded no maternal deaths, but had a fetal mortality of 26 per cent. Forty-seven of these cases were followed for six months to two and a half years after delivery, only 1 showing definite hypertension and albuminuria.

In an analysis of 168 patients treated for eclampsia at the Boston Lying-in Hospital from 1915 through 1934 Teel and Reid were able to determine that the maternal mortality was six times as high in women with eclampsia who were known to have had pre-existing hypertension or nephritis as in those known to have been normal before and during early pregnancy. Among 127 patients who had survived eclampsia there were 8 subsequent deaths. 3 had recurrent toxemia (including 2 with recurrent eclampsia), while 3 of the remaining 5 patients had hypertensive disease and 1 may have had nephritis. Eighty patients were subjected to follow up studies. 27 per cent had some degree of hypertension and 9 per cent albuminuria.

The studies outlined in the four preceding paragraphs as well as those reported by Dieckmann and Brown²² and others, bring to our attention the fact that some progress is being made toward classifying the types of hypertensive and albuminuric conditions associated with pregnancy. They indicate that pregnancy may be superimposed upon a pre-existing hypertension, that it may develop a latent hypertension which outlasts the duration of gestation indefinitely, that it may be carried success-

fully to viability in the presence of a pre-existing glomerulonephritis, that pregnancy, especially in the case of excessive multiparity and advancing age, may add appreciably to the damage done to the vascular and renal systems, as well as to the odds against the delivery of a living baby at or near term, and finally that pregnancy, whether or not it is superimposed upon a hypertensive or nephritic background, may be complicated by a syndrome of mysterious origin which for the want of a more specific etiology we must continue to call pre-eclampsia, if unassociated with convulsions, coma or both, or eclampsia, if such association occurs. Stander and Kuder's⁸³ concept of the low-reserve kidney may be construed as mild pre-eclampsia, though the validity of the assumption of renal primacy in this syndrome is in any event debatable. What the nature of the factor is which causes pre-eclampsia or eclampsia to occur in late pregnancy is still beyond our ken, but both the clinical behavior of these conditions and the morbid vascular physiology associated with them render the hypothesis of a circulating factor which acts as a vascular toxin, as emphasized by Page and Ogden,⁸⁴ hard to eliminate completely from consideration.

At all events, an encouraging start has been made. By the combined and co-ordinated efforts of the internist and the obstetrician and of medical and maternity clinics, or by the constant observation and study of obstetric patients before, during and for years after their childbearing careers by the physicians who attend them, we have strong encouragement for the belief that a more rational management of hypertensive and albuminuric pregnancies may be attained, and that prognosis for the life and future health of the mother and infant may be more clearly defined.

CASE RECORDS OF THE MASSACHUSETTS GENERAL HOSPITAL

ANTEMORTEM AND POSTMORTEM RECORDS AS USED
IN WEEKLY CLINICOPATHOLOGICAL EXERCISES

FOUNDED BY RICHARD C. CABOT

TRACY B. MALLORY, M.D., *Editor*

CASE 26021

PRESENTATION OF CASE

A fifty-six-year-old housewife was admitted to the hospital complaining of pain in the chest of twenty-four hours duration.

The patient stated that she had not been "really well" for ten years before admission. She had experienced vague, transient abdominal and joint pains, had felt weak and had noted nocturia one to three times. She, however, was able to perform her housework until eight months before admission when she developed a severe cold that left her debilitated, anorectic and listless. She began to notice nervousness, dizziness, throbbing headaches and blurring of vision. These complaints increased in severity until four months before admission when she entered the Out Patient Department. The physical examination revealed a well-developed and nourished woman in no acute distress. The fundi showed narrow, tortuous, silvery arteries, with marked changes in caliber. There were small areas of white exudate in the macular regions of both eyes. She was edentulous. The heart was enlarged to the left and downward, with the apex 11.5 cm from the mid-sternum. A soft systolic murmur was heard over the apex, with the aortic second sound louder than the pulmonic. The rhythm was regular, the sounds of good quality, and the blood pressure 254 systolic, 134 diastolic. The lungs, abdomen and remainder of the examination were negative. The blood examination showed a red-cell count of 4,900,000 with 80 per cent hemoglobin, and a white-cell count of 12,000 with 74 per cent polymorphonuclears. The urine showed a specific gravity of 1.020, a +++ albumin test and an abundant growth of *Bacillus coli* in the catheterized specimen, there were occasional granular and hyaline casts. A flat abdominal film showed a small right kidney and a large left kidney shadow. There were degenerative changes of the lumbar spine and evidence of arteriosclerosis. A soft tissue mass in the true pelvis was thought to be an enlarged uterus. There was fairly prompt excretion of dye on the right side, the kidney pelvis were normal in size and shape, and the ureters were incompletely demonstrated. The patient was treated symptomatically, but her

complaints progressed. One month before admission to the hospital daily vomiting began, and persisted. Her vision failed, and she became dyspneic, and orthopneic, but noticed no edema. She felt very drowsy but, at the same time, restless and was unable to sleep. One week before entry she noted that her urinary output had become scanty. One day before admission the abrupt onset of a severe substernal and mid-epigastric pain appeared, there was no radiation to the neck, jaw or arm. The pain was so agonizing that it caused her to "double up," and she felt choked and as though she could not breathe. The pain kept her awake all night, but diminished somewhat on the morning of admission. There was an associated severe headache. She had lost 30 pounds during the eight months before admission. The remaining past, family and marital histories were noncontributory.

The physical examination revealed a tall, well-developed woman with loose skin and evidence of recent weight loss. She was listless and responded poorly. The breath was urinous. The fundi showed areas of exudate, silver wire arteries with marked changes in caliber, and blurred optic disks with loss of physiologic cupping. The heart was enlarged to the left and downward, with a systolic murmur over the precordium. There was also a harsh scratching sound heard in systole over the pulmonic area and along the left border of the sternum. The blood pressure was 240 systolic, 140 diastolic. The radial and brachial arteries were extremely hard. By vaginal examination the fundus of the uterus seemed to be about twice its normal size, but was firm and freely movable, the cervix was normal.

The temperature was 99°F., the pulse 90 and the respirations 22.

Examination of the blood showed a red-cell count of 3,100,000 with 69 per cent hemoglobin and a white-cell count of 15,300 with 94 per cent polymorphonuclears. The urine showed a constant ++++ albumin test, with the sediment containing innumerable white cells. A urine concentration test demonstrated a maximum specific gravity of 1.014. A culture of a catheterized specimen showed no growth. The serum nonprotein nitrogen was 130 mg per 100 cc. The serum calcium was 7.7 mg per 100 cc., and the phosphorus 14.0 mg. A lumbar puncture was normal except for a ++ ammonium sulfate flocculation test and a total protein of 63 mg per 100 cc. An electrocardiogram taken one day after admission showed a low T₁, a diphasic T and an inverted T₃ with Q₃ small, ST₁ and ST₂ slightly depressed and slight slurring of QRS. A retrograde pyelogram

on the left showed the tip of the catheter at the level of the upper margin of the sacrum, the kidney pelvis was moderately dilated, the calyces were irregularly outlined, and the ureter was not dilated. The patient ran a slow, steadily downhill course. A few hours after admission she became more restless, and dyspneic. She became cold and gray, and was sweating. The pericardial friction rub disappeared, and the pulmonary second sound became louder than the aortic. The right lung filled with fine crackling inspiratory rales, and a gallop rhythm appeared at the apex. The blood pressure remained at 280 systolic, 140 diastolic. She became irrational, stuporous and finally, after a few days, comatose. Her serum nonprotein nitrogen rose to 205 mg per cent. The temperature gradually rose to 100, then to 103°F, where it remained for three days until she died on the tenth hospital day. The pulse varied between 80 and 100, and the respirations from 12 to 25. A few hours before death she developed a confluent erythematous eruption over the entire body.

DIFFERENTIAL DIAGNOSIS

DR WILLIAM B BREED This on the surface seems to be a perfectly orthodox case. It is that of a fifty-six-year-old woman with ten years of disability and increasing symptoms which suggest arteriosclerosis, hypertension and nephritis. Through the period of the visits to the Out Patient Department there seems to be very little to comment on except the question of the condition of the left kidney, which is not clearly described. In the Out Patient Department the urine at first showed an abundant growth of colon bacilli but no pus, later on, much pus and a sterile culture. She had no substernal or epigastric pain until just before she came into the hospital, so that we do not have to consider anything else but progressive arteriosclerosis with hypertension and nephritis, except possibly the question as to what part one kidney played in the production of hypertension. The report on the intravenous pyelogram is not at all conclusive, and I should like a little more information on that.

DR GEORGE W HOLMES We have here only the films of the retrograde pyelogram, those of the previous intravenous pyelogram are missing. The report of the latter speaks of a large left kidney and a small right one, it mentions fairly prompt excretion of the dye by the right kidney and implies but does not actually state that excretion was delayed on the left. They did not describe any abnormality of either pelvis but nevertheless interpreted the findings as suggestive of

left hydronephrosis. I should not care to accept such an opinion without reviewing the films myself.

These are the films of the retrograde pyelogram. We have no films that are free from motion, and I imagine that they were taken with low-amperage apparatus. The left kidney is a little larger than the right. The right is small, and the left about normal in size. I should not interpret this pyelogram as being abnormal. The left pelvis does look large, but if the man who injected it used a little more pressure than usual he could make a normal kidney pelvis look as large as that and assume that shape. Whatever change you have there might be due merely to spasm from overinjection. The kidneys may be diseased, but I am not willing to make a diagnosis of anything in particular from the evidence.

DR WILLIAM B BREED She may have had infection in both kidneys or only in one. While in the hospital the fever was indicative of a generalized infection. Up to the day before entry this is a perfectly straightforward story of increasing renal failure and hypertension. The episode which occurred on that day could have been due to one of three important things: coronary occlusion, pericarditis or pulmonary embolus. We do not need to consider anything but pericarditis if we are going to be consistent. The pain is perfectly admissible. She did not have shock, she had no fall in blood pressure. At that time there was a systolic friction rub over the pulmonary area and along the left sternal border, but no evidence of a large pulmonary embolus or of a coronary episode.

Before this exercise, I took the occasion to talk with Dr Bland about the electrocardiogram, without telling him the story, because I was confused about it. I think it would be fair to ask him now, knowing the story, to comment further. She had had no digitalis to produce the changes. She did have uremia, which might explain them. The only thing that was odd about it was the absence of left-axis deviation, in the face of a large left ventricle.

DR EDWARD F BLAND This tracing is well described in the record. It is abnormal but without a very characteristic configuration. ST₁ and ST₂ are definitely low and diphasic. T₁ is a little inverted. The QRS complexes are just a little slurred but within the accepted normal. The chest lead is normal. The PR interval is at the upper limit of normal, 0.2 sec, which was not mentioned in the record. With these changes one would suspect that digitalis was responsible, but the patient is said to have had none. These

changes in the ST waves in all three leads make one wonder a little about pericarditis. Uremia also will change the T waves, as well as other severely toxic states. If this patient had a big heart secondary to hypertension, it is a little unusual not to have had a little more indication of left axis deviation, but I do not believe we had better put too much weight on that.

DR. BREED: Would the presence of pericarditis or pulmonary infarct destroy the evidence of left axis deviation that might have been there?

DR. BLAND: If there had been left axis deviation due to hypertension, it would have taken a considerable amount of dilatation of the right side of the heart to balance it in a normal direction. We sometimes see such a condition in young people with severe rheumatic fever who get acute dilatation of the heart. One also has to consider that there may have been very clear changes due to coronary disease before the last episode, which may in turn have masked them.

DR. PAUL D. WHITE: I should consider this an abnormal record. Dr. Breed will remember a patient whose record improved in appearance a good deal while coronary disease actually increased, due to a compensating lesion in a different part of the heart. With an old apical infarct the T waves in Lead I were inverted, but a fresh, basal infarct made them upright again and so look better. Actually the patient was sicker as a result of the new lesion.

DR. JOHN H. TALBOTT: Is it clear that the patient had not had digitalis before the electrocardiogram was taken?

DR. TRACY B. MALLORY: On the day before at three in the afternoon, the patient had been given 9 gr. Some time earlier, while being followed in the Out Patient Department, she had been given digitalis, but she had not taken any for several months.

DR. BREED: In any case, digitalis may have had an effect on the tracing. The electrocardiogram does not give us much help in determining what was going on here except, I think, in ruling out coronary occlusion.

I shall comment a minute on the blood chemical findings. At first glance the figures suggest hyperparathyroidism, but the phosphorus is a good deal higher in proportion to the depression of the calcium than one finds in that condition. I think these figures merely represent a very severe acidosis, which is always present with this degree of uremia.

If I am right, the first episode of pain before she came in, is to be accounted for by pericarditis associated with uremia. The pulmonary

second sound became much louder than the aortic, a change which suggests that in addition to uremia and pericarditis there may have been pulmonary infarction toward the end. Of course, this change in the pulmonary second sound is very striking, if the record is true, and I think it is worth taking seriously. At about the same time they found crackling inspiratory rales, and a gallop rhythm in the heart. There is no note of distended neck veins. If she had had distended neck veins it would make it a little easier to conclude that there was pulmonary infarction. I am rather inclined to think that this last episode of pain is different from the one she had before she came in, and that it was perhaps due to pulmonary infarction. We know she had infection in the genitourinary tract, which involved one or both kidneys. She had been sick a good while, and there is every reason to expect that she might have had an embolus, septic or not.

So to summarize, she had arteriosclerosis and uremia, the latter probably on an arteriosclerotic hypertensive basis. Not being able to accuse one particular kidney I cannot include it as a cause of the hypertension although there might perfectly well have been a contributory infection in the kidney. As a terminal event pericarditis supervened. I suspect that in addition there may have been terminal pulmonary infarction.

DR. WHITE: I should like to comment on the scratchy sound in systole over the pulmonary area that disappeared. We have observed it a number of times in cases without pericarditis but with acute pulmonary embolism and resulting dilatation of the pulmonary artery. I think it might be explained on that basis in this case. In other words, the first attack might have been due to pulmonary embolism rather than pericarditis and another attack occurred later.

DR. BREED: Apparently the friction rub lasted ten days or more. She was in the hospital for ten days, and it only disappeared the day before she died. One would not expect a pulmonary infarct to remain constant for ten days.

DR. WHITE: True, but there may be prolonged dilatation of the pulmonary artery, as in cases of thyrotoxicosis. I have not known of its persistence for as long as ten days in pulmonary embolism, however.

DR. TALBOTT: I saw the patient only a couple of days before she died. The pericardial friction rub had disappeared.

DR. WHITE: So it may have been brief.

DR. BREED: It could have been due to pericarditis and still have disappeared.

DR. WHITE: I was trying to help you out with

one diagnosis so you would not have to make two

DR BREED Then you would like to exclude pericarditis, if possible?

DR WHITE Yes The pericardial friction rub in uremia is near the apex and the lower end of the sternum rather than over the pulmonic valve area

DR BLAND Might I ask about pain associated with pericarditis Is it usually as agonizing and severe as it apparently was here? My impression is that most people with pericarditis have no severe pain

DR BREED I should agree, but it may be very severe

DR WHITE The pericarditis of uremia is painless, is it not?

DR BREED Not always

DR MALLORY A significant number of patients with pericarditis reach the operating table and have their gall bladders or stomachs explored

DR CHARLES L SHORT That point came up before at one of these conferences It was said that many of these patients were stuporous and did not notice the pain, but that in conscious patients it was a common finding

DR BREED May I ask whether this electrocardiogram rules out a pulmonary embolism in the first episode?

DR BLAND There are no characteristic changes of acute pulmonary embolism in the record

DR WHITE It may be too late for them The record was taken twenty-four hours after the attack The electrocardiographic evidence in the acute cor pulmonale may last only a few hours

CLINICAL DIAGNOSES

Uremia
Vascular nephritis
Coronary occlusion?

ANATOMICAL DIAGNOSES

Vascular nephritis, chronic
(Uremia)
Pericarditis, fibrinous, acute
Cardiac hypertrophy, hypertensive type
Arteriosclerosis of coronaries, aorta and renal vessels
Hydronephrosis, left, slight
Leiomyomas of uterus
Cystitis

PATHOLOGICAL DISCUSSION

DR MALLORY Cases of this sort are difficult to interpret in life and equally difficult to interpret after postmortem examination This patient did have a pericarditis, an acute fibrinous one, and did not have any pulmonary emboli So I think we have to assume that the rub and pain were both due to pericarditis She had a moderate amount of coronary sclerosis but no occlusion and no areas of infarction The heart was considerably hypertrophied, weighing 600 gm, and the hypertrophy was predominantly left ventricular So it seems she would have had a left-axis deviation

The kidneys are rather more difficult to interpret They were a little small—one weighed 120 gm, the other 135 gm The pelvis of the left kidney seemed to us very slightly dilated, and the calyces very slightly blunted On the right the pelvis was even more questionable, we were not sure whether it was dilated The renal arteries on both sides showed rather marked atheromatosis, and on the left, one of the atheromatous plaques seemed definitely to obstruct the lumen of the artery Both kidneys showed adherent capsules and granular surfaces, and on microscopic examination, an extremely severe grade of vascular nephritis Whether or not they show minimal evidence of inactive and healed pyelonephritis, I would not dare to say I can see nothing that strikes me as convincing evidence of such a diagnosis, although I think it is the type of lesion that might be interpreted as such

DR WHITE Was the pericarditis fibrinous and not purulent?

DR MALLORY It was fibrinous

DR HOLMES Was there any disease of the mucous membrane of the pelvis of the kidney?

DR MALLORY No

DR WHITE An important lesson from this case is the correction of the current impression, which had been my own also, that the pericarditis of uremia is painless Terminal heart failure may explain the late signs which simulated a final pulmonary embolism

CASE 26022

PRESENTATION OF CASE

A sixty-three-year-old Italian candy maker was admitted complaining of difficulty in eating solid food

Four years before entry the patient had retired from active business but felt quite well at that time For the next two years his health remained good, but thereafter he gradually developed ma

laise and progressive weakness. There was slight increasing dyspnea with exertion but no cough or expectoration. For about eight months prior to admission he had swelling of the ankles developing in the afternoon and subsiding during the night. There was no associated pain or intermittent claudication. Four months before entry he began to have nocturia of four or five times, with a diurnal frequency of five or six times. There was some dysuria, but the urinary symptoms were improved following medication two weeks before admission. Two months before entry he began to have difficulty in swallowing. There was some question in the recorder's mind as to whether this was obstruction or merely an extreme anorexia. The patient stated that he would take a mouthful of food and then expectorate it. He was able, however, to ingest liquids without difficulty. There was some gaseous eructation but no nausea or vomiting. During the four months before coming to the hospital he was slightly constipated and took a laxative every other day. This produced two bowel movements daily, which were not watery and did not contain blood. The stools were rather light colored, but there was never any jaundice. Two months before entry he first noted that his abdomen was larger than usual. There was no pain except for occasional lower abdominal cramps associated with bowel movements. A week before entry he began to cough up small amounts of mucoid material. Occasionally a little blood was expectorated in the morning. The cough often awakened him at night and he had difficulty in getting his breath until he raised some of the mucoid material. At no time was the patient confined to bed. His weight five years previously was 188 pounds, and on entry 176 pounds.

Physical examination showed a well nourished florid man who coughed frequently. There were numerous telangiectases on the face, the skin, nailbeds and mucous membranes were hyperemic. Oral hygiene was poor, and the tongue was dry and furred. Percussion of the chest showed that the diaphragm was higher than normal, with the left leaf higher than the right. There was dullness at both apices posteriorly, and inconstant rales were audible at the right apex, no other pulmonary signs were noted. The heart was slightly enlarged to the left, and the sounds were distant in character; no murmurs were heard. The abdomen was protuberant, and there was a reddish-blue, reducible, umbilical hernia. A fluid wave was elicited and there was shifting dullness in the flanks. The liver and spleen were not palpable, but there was tenderness in the right upper quadrant. The left testicle was small, and the scrotum over its posterior surface pre-

sented a rough hard area. There were numerous varicosities of the lower extremities, and pitting edema up to the hips.

The temperature was 99.8°F, the pulse 100, and the respirations 25.

Examination of the urine showed a specific gravity of 1.032, with a slight trace of albumin and a green precipitate with the Benedict test. The blood showed a red-cell count of 4,600,000 with a hemoglobin of 90 per cent, and a white-cell count of 7590 with 81 per cent polymorphonuclears. Several sputum specimens contained blood but were negative for tubercle bacilli. Three stool specimens gave negative reactions to the guaiac test. A blood Hinton test was negative. The icteric index was 5, and the van den Bergh test gave a direct reaction. A liver function test showed 40 per cent retention of dye, and the Takata Ara reaction was strongly positive. A tuberculin test was negative.

X-ray examination showed a diaphragm with limited motion. There were increased markings in the medial portions of both lower lung fields and a hazy, partially calcified dullness in the lateral portion of the first right intercostal space. The heart was not enlarged, but the left ventricle appeared to be hypertrophied. The aorta was tortuous and slightly widened, and showed marked calcification. There was no evidence of esophageal varices, but the lower end of the esophagus was dilated and there was a small hiatus hernia.

On the second hospital day 3500 cc. of slightly cloudy, pale yellow fluid was removed by abdominal paracentesis; this formed a pellicle on standing. The specific gravity was 1.005, there were 300 white blood cells per cubic millimeter, of which 75 per cent were lymphocytes and 25 per cent polymorphonuclears. The patient continued to run a fever up to 100°F and on the fourth hospital day expectorated about half a cupful of reddish-brown sputum. Six days later the temperature rose sharply to 103°F, and the respirations to 45. There was dullness at the right base. The breath sounds were diminished, and a few crackling rales were heard. Later the dullness became increased and bronchial breathing was heard in the same region. His temperature remained elevated, and the chest signs persisted. His condition became progressively worse, and he died on the thirteenth hospital day.

DIFFERENTIAL DIAGNOSIS

DR. ALFRED O. LUDWIG. The differential diagnosis in this case presents considerable difficulty because of the fact that his symptoms are referable to several systems. The most important features in this history seem to me to be the increas-

ing dysphagia, the dyspnea, the cough and later hemoptysis, the malaise and weight loss, the abdominal symptoms, the increase in size of the abdomen, the cramps and constipation, and finally the increasing edema of the lower extremities.

The record tells us that this man had not lost much weight. The telangiectases mentioned are not unusual in older individuals, but are thought by some to be indicative of liver disease. The examination of the lungs indicates that both leaves of his diaphragm were high, and further information makes it likely that they were elevated by the presence of fluid in the abdominal cavity. I am inclined to discount the lung findings mentioned at this point. Along with everything else, the presence of an umbilical hernia is confirmatory evidence that there was an increase in intra-abdominal pressure, in this case due to fluid. I do not know how to interpret the findings in the testicle and scrotum. The edema of the lower extremities was probably due to the same cause as was the ascites.

The laboratory examination proved that this individual did not have any marked degree of renal disease, as he was able to concentrate up to a specific gravity of 1.032. This is unusually high and may be partially explained on the basis of glycosuria, although he may have been somewhat dehydrated at the time this specimen was collected, or was unable to excrete water normally because of the edema. The examination of the blood was normal, but the presence of blood in the sputum draws our attention back to the lungs, and it is difficult to escape the idea that there must have been some lesion there to explain this finding. The absence of occult blood in the stool is a bit of evidence against a lesion which would cause bleeding into the gastrointestinal tract, such as cancer of the stomach or bowel, and also against varices in the esophagus, at least against bleeding varices. The icteric index and van den Bergh tell us that there was a disturbance of the liver, and as we know that there was bile in the stools, the bilirubinemia could not have been due to an obstruction of the bile passages but must have been secondary to disease within the liver. This is further substantiated by the fact that he had a markedly impaired liver function, as evidenced by the retention of 40 per cent of the dye and also by the strongly positive Takata-Ara test. This is good evidence of severe liver damage, although it does not tell us anything about its cause.

The x-ray films of the lungs are consistent with the presence of an old tuberculosis, but I cannot tell from them whether there was active tuberculosis at the time of his entry. The findings in

the heart and aorta I interpret as consistent with his age. I should like to know more about the dilatation of the lower end of the esophagus. One wonders, for instance, if there might have been some cause for obstruction below. Certainly the record should so state, if there was any evidence of esophageal tumor. A hiatus hernia is not uncommonly present, and I do not believe that it contributes to his symptoms.

The findings in the ascitic fluid are those of a transudate, but I do not believe that ordinary transudates, such as one would expect to find in uncomplicated hepatic cirrhosis, usually contain so many white blood cells, and their presence suggests a complicating low-grade peritonitis, which is not uncommon in the presence of cirrhosis of the liver.

The terminal course of this patient again leads us back to the lungs. The description is that of a pneumonic consolidation at the right base, and this condition seems to have led to his death.

Is it possible to tie up all these findings and to explain the course of the disease on the basis of one diagnosis? I do not believe that it is. In the presence of marked impairment of liver function, jaundice and edema, I do not see how one can escape the diagnosis of cirrhosis of the liver. We do not know if he had an alcoholic history, but that is not necessary for the development of cirrhosis. However, such a diagnosis cannot explain the hemoptysis, cough and dyspnea, and terminal lung findings, and we must conclude that the dullness and rales heard at the apices at the time of admission are more important than I was at first inclined to believe. These, plus the x-ray findings, as well as the persistent hemoptysis, strongly suggest the presence of pulmonary tuberculosis. If this is true, then even the terminal event could be explained on the same basis, namely, a tuberculous pneumonia, arising by a sudden massive bronchial spread. The presence of the white cells in the peritoneal fluid might be interpreted as evidence of a low-grade tuberculous peritonitis, although there is nothing else to suggest it, and implies that he had a miliary spread at the end. This is possible, but we have no way to be certain. The negative tuberculin test is against the diagnosis, but may occur occasionally in the presence of miliary tuberculosis.

Is there any other way in which we can explain his symptoms? I suppose that one should consider tumor of the lung. Metastatic carcinoma does not usually invade bronchi and therefore does not cause hemoptysis. It would seem to me to be very unlikely that this man had a large primary bronchial carcinoma without there being

more evidence of it on physical or x-ray examination

Could he have had tumor elsewhere? If present, it must have invaded the liver to the extent that it caused marked impairment of function, and in that case it would seem likely that the liver would have been enlarged and that metastatic masses would have been palpable. It is possible of course that he may have had a primary hepatoma arising on a cirrhotic liver, a favorable condition for such an event. I do not believe that we have enough evidence for this diagnosis. Should one consider that tumor may have arisen from the testicle? If it is of any importance at all, I think it is more likely that the mass felt there was tuberculous, and part of a general tuberculosis. How about the terminal dysphagia? It may have been a part of his cirrhotic symptom complex but I do not recall having seen such marked dysphagia from that cause alone. As no intrinsic cause was demonstrated, and there does not seem to have been a paralysis of the pharyngeal muscles, one must consider an extrinsic cause for this symptom. Possibly there were lymph nodes which were causing pressure on the esophagus. If so they should have been demonstrated by x-ray. I do not believe that this is an entirely satisfactory explanation. In the absence of a blood-sugar determination it is not possible to say whether the glycosuria was due to diabetes mellitus or related to the liver disease. It was more likely due to the latter. There was no evidence of renal tuberculosis.

It is possible that the liver impairment was tuberculous in origin, either due to large tuberculous foci in the liver or to miliary tuberculosis. If he had miliary tuberculosis, it must have been of very recent origin, as his whole story is much more that of slowly developing symptoms secondary to hepatic cirrhosis, with perhaps a terminal lighting up of an old tuberculous process in the lung.

CLINICAL DIAGNOSES

Cirrhosis of liver
Bronchopneumonia
Ascites
Malignancy of lung?
Tuberculosis of lung?

DR LUDWIG'S DIAGNOSES

Portal cirrhosis of liver
Ascites and peripheral edema
Pulmonary tuberculosis (apical and tuberculous bronchopneumonia)
Tuberculous peritonitis?
Miliary tuberculosis?

ANATOMICAL DIAGNOSES

Cirrhosis of liver, alcoholic.
Ascites
Lobar pneumonia
Pulmonary tuberculosis, healed
Peritonitis, chronic aseptic
Nephritis, chronic vascular, slight.

PATHOLOGICAL DISCUSSION

DR TRACY B. MALLORY The clinicians on the ward who were in charge of this patient reached essentially the same conclusion as that of Dr Ludwig. The primary condition was obviously cirrhosis of the liver. The organ was moderately hypertrophied weighing 1950 gm. Its surface was definitely granular, with fairly uniform nodules measuring from 1 to 4 mm in diameter. It was markedly firm and cut with considerable difficulty, thus indicating extensive fibrosis. On microscopic examination it was entirely consistent with an alcoholic cirrhosis, and the lack of a definite history may well have been due to the language difficulty and the necessity of taking his story through an interpreter. Considering the severe degree of the cirrhosis, it was surprising that the spleen was not enlarged. It weighed only 160 gm and did not show any significant degree of the fibrotic change which is usual in cases of portal obstruction. The esophagus also showed little abnormality, although the prosector thought there was a slight dilatation of some of the mucosal veins; certainly there were no definite varices. In the clinical examination it was noted that the veins of the anterior abdominal wall were unusually prominent, and it is possible that most of the collateral circulation had developed in this direction rather than through the splenic vein and the esophageal vessels. His omentum was very densely adherent in both flanks and beneath the old herniorrhaphy wound which may well have permitted an extensive collateral circulation to have developed. We found nothing which would explain the dysphagia. An old apical tuberculous process was present, but there was no definite evidence of activity. The terminal event was a lobar pneumonia in the right middle and lower lobes. The heart was not hypertrophied, and the coronaries showed moderate atherosclerosis but no significant narrowing of their lumens. The kidneys showed a moderate grade of vascular nephritis, and unfortunately, we did not explore the testicle. The peritoneal fluid was very faintly turbid, and the peritoneal surfaces tended to be slightly granular, nothing was found, however, to suggest a true infectious peritonitis.

THE TUBERCULIN PATCH TEST

IN 1937 Vollmer and Goldberger¹ described a tuberculin patch test for children and found it simple, harmless and reliably approximating the accuracy of the Pirquet test. The material for this Vollmer patch test consists of a wide strip of adhesive tape on which have been placed two small squares of filter paper previously saturated with Old Tuberculin, with a control square saturated with glycerin broth between them. The tape with its dried squares is firmly applied to the skin, previously cleansed with ether, benzol or acetone. Natural moisture of the skin (insensible perspiration) liquefies the tuberculin concentrate, which can then be absorbed by the skin, producing a tuberculin reaction. The tape with its squares is

removed forty-eight hours later, and the test is read forty-eight hours after removal. A few tests may not become positive until the third or fourth day.

Vollmer and Goldberger² carried out a comparative study of the patch test and the Mantoux test in 678 children. Their results showed 100 per cent conformity of the patch test with the Mantoux test using 0.1 mg. of Old Tuberculin or the first test solution of Purified Protein Derivative. Hart³ in England found similar results in comparative studies on 536 children, but the patch test gave fewer positive reactions than did strong dilutions (10 mg.) of Old Tuberculin. Wolff and Hurwitz⁴ tested 964 children under sixteen years of age. They found no discrepancy between the patch test and Mantoux test in cases with active tuberculosis, but one of 18 per cent in the series as a whole. Another comparative study on children twelve to sixteen years of age is reported in this issue of the *Journal*.

Experience is thus accumulating to show that the tuberculin patch test is a new and important addition to our armamentarium in the early diagnosis of tuberculosis. It is a test that is simple and painless to carry out, and one that requires no instruments to perform. Severe local and constitutional reactions have not been reported, and there is no danger of infection. There is little objection to its use, and it is a test that should prove of value to the practitioner in the use of tuberculin for the discovery of contact cases of tuberculosis. The difficulties that are entailed in the preparations for a Mantoux test and the ever-present fear of the "needle" by both parents and children too often lead to its omission as a diagnostic procedure.

The conformity of the tuberculin patch test to the Mantoux test using 0.1 mg. of Old Tuberculin or the first test solution of Purified Protein Derivative has been well established in children, but comparative studies in adults are lacking. Until more widespread investigations have been carried out it is probably still necessary, as recommended by Vollmer and Goldberger,² to retest those negative to the patch test with 10 mg. of Old Tuberculin.

culin or the second test solution of Purified Protein Derivative. Where there is any doubt regarding the presence of tuberculous infection the Mantoux reaction remains the final and decided test.

INDUSTRY AND SYPHILIS

In the present campaign against syphilis attention should be called to the important relation of industry, as represented by employers, to syphilis. Syphilis produces incapacity in workers in two stages first, in the early stage when it is communicable, and, secondly, in the late stage when manifestations of the disease produce a lowered earning capacity. If early syphilis is adequately treated the contagiousness quickly disappears and the individual can return to work with an excellent chance of continuing an undiminished earning capacity. If employers see to it that such a worker continues his treatment and keep him on the job, they can retain such people as valued workers and aid in preventing the later disabling consequences which may result in the worker's becoming a public charge because of cardiovascular or cerebrospinal complications. Surveys have shown that in patients observed over a ten or twenty year period no cases of syphilitic heart disease developed among those who had received proper treatment in the early stages, while 34 per cent of those having no treatment developed cardiac manifestations. Furthermore, in these series only 1.6 per cent of the properly treated patients showed central nervous-system disease, while in the untreated cases 17 per cent of the patients developed syphilis of the central nervous system. All in all, it has been found that adequate treatment early in the disease will prevent the manifestations of late syphilis in more than 80 per cent of all cases.

In the majority of cases discovered at present

the patients are found to have the latent and asymptomatic type of syphilis, and the late complications may also be prevented in these cases by adequate treatment. Some industries have already established clinics for the treatment of infected employees and their families and are requiring routine serological examinations. These employers are not discharging such employees. They require them to continue treatment. They preserve the relations of the worker and the medical department in the best professional tradition. Such employers are to be commended for thus contributing to the advance of preventive medicine.

This matter has been considered of sufficient importance by the United States Public Health Service* to warrant the advocacy of a special program concerning the handling of syphilis among employees. The recommendations are

That routine blood tests be taken on applicants for employment.

That routine blood tests be taken at the time of periodic re-examination of employees.

That industry, with its compact organization develop a vigorous educational program.

That industry extend its educational campaign into the field of prophylaxis.

That responsibility upon the industrial medical officer to see that adequate modern treatment is available to employees at prices ordinary wage earners can afford be fully recognized. If such treatment is not available in private practice or at public clinics, industrial medical service should undertake such treatment.

That syphilis be handled at all times as merely another communicable disease. The privacy of relations between the worker and the medical service should be preserved in the best professional tradition. When treatment is properly required in ordinary cases this cannot be regarded as ground for discrimination of any kind against employees.

If all physicians having part-time or full-time positions with industrial concerns are willing to co-operate in urging the adoption of this program by industry, much will be gained toward the eradication of syphilis and the prevention of lowered earning capacity due to its late manifestations.

Release (No. 15-91) from United States Public Health Service, dated January 6, 1939.

MEDICAL EPONYM

ADDISONIAN ANEMIA AND ADDISON'S DISEASE

At a meeting of the South London Medical Society on Thursday, March 15, 1849, according to an unsigned report of the proceedings published in the *London Medical Gazette* (N S 8 517-518, 1849), it is stated

Dr Addison, at the request of the President, proceeded to describe a remarkable form of anaemia, which, although incidentally noticed by various writers, had not attracted, as he thought, by any means the attention it really deserved. It was incident to adult males usually occurs between the ages of twenty and sixty more frequently commencing insidiously and proceeding very slowly relaxation and flabbiness, rather than wasting of the flesh, being one of the most remarkable features of the disorder. Dr Addison next proceeded to give the details of several cases [of another disease] which had fallen under his own immediate observation. In only two of these did the patients recover. In three cases only was there an inspection of the body after death, and in all of them was found a diseased condition of the supra-renal capsules.

The above is the first published reference to Addison's description of these two diseases.

Thomas Addison (1793-1860), then senior physician to Guy's Hospital, London, published his famous monograph, *On the Constitutional and Local Effects of Disease of the Supra-Renal Capsules* (London: Samuel Highley), in 1855, in which appear the following accounts (pages 2 and 3, and 4 and 5).

For a long period I had from time to time met with a very remarkable form of general anaemia, occurring without any discoverable cause whatever, cases in which there had been no previous loss of blood, no exhausting diarrhoea, no chlorosis, no purpura, no renal, splenic, miasmatic, glandular, strumous, or malignant disease. Accordingly, in speaking of this form of anaemia in clinical lecture, I, perhaps with little propriety, applied to it the term 'idiopathic,' to distinguish it from cases in which there existed more or less evidence of some of the usual causes or concomitants of the anaemic state.

The disease presented in every instance the same general character, pursued a similar course, and, with scarcely a single exception, was followed, after a variable period, by the same fatal result. It occurs in both sexes, generally, but not exclusively, beyond the middle period of life, and so far as I at present know, chiefly in persons of a somewhat large and bulky frame and with a strongly marked tendency to the formation of fat. It makes its approach in so slow and insidious a manner, that the patient can hardly fix a date to his earliest feeling of that languor, which is shortly to become so extreme. The countenance gets pale, the whites of the eyes become pearly, the general frame flabby rather than wasted, the pulse perhaps large, but remarkably soft and compressible, and occasionally with a slight jerk, especially under the slightest excitement, there is an increasing indisposition to exertion, with an uncomfortable feeling of

faintness or breathlessness on attempting it, the heart is readily made to palpitate, the whole surface of the body presents a blanched, smooth and waxy appearance, the lips, gums and tongue seem bloodless, the flabbiness of the solids increases, the appetite fails, extreme languor and faintness supervene, breathlessness and palpitations being produced by the most trifling exertion or emotion, some slight oedema is probably perceived about the ankles, the debility becomes extreme, the patient can no longer rise from his bed, the mind occasionally wanders, he falls into a prostrate and half torpid state, and at length expires nevertheless at the very last, and after a sickness of perhaps several months' duration, the bulkiness of the general frame and the amount of obesity often present a most striking contrast to the failure and exhaustion observable in every other respect.

With, perhaps, a single exception, the disease, in my own experience, resisted all remedial efforts, and sooner or later terminated fatally. On examining the bodies of such patients after death, I have failed to discover any organic lesion that could properly or reasonably be assigned as an adequate cause of such serious consequences.

It was whilst seeking in vain to throw some additional light upon this form of anaemia, that I stumbled upon the curious facts, which it is my more immediate object now to make known to the Profession.

The leading and characteristic features of the morbid state to which I would direct attention are anaemia, general languor and debility, remarkable feebleness of the heart's action, irritability of the stomach, and a peculiar change of colour in the skin, occurring in connexion with a diseased condition of the "supra-renal capsules."

This discoloration pervades the whole surface of the body, but is commonly most strongly manifested on the face, neck, superior extremities, penis and scrotum, and in the flexures of the axillae and around the navel. It may be said to present a dingy or smoky appearance, or various tints or shades of deep amber or chestnut brown, and in one instance the skin was so universally and so deeply darkened, that, but for the features, the patient might have been mistaken for a mulatto.

FATAL PUERPERAL SEPSIS FOLLOWING
NORMAL DELIVERY

Mrs. M. C., a thirty-six-year-old woman, was admitted to the hospital on July 14, 1926, with a temperature of 102.6°F and a pulse of 100. Her fifth baby had been delivered normally at home thirteen days previously. She stated that, after

*A series of selected case histories by members of the section will be published weekly. Comments and questions by subscribers are solicited and will be discussed by members of the section.

having been well since the birth of the baby, she felt poorly and complained of a good deal of pain and soreness in the lower abdomen on getting out of bed on the tenth day. The baby died on that day.

The family and past histories were not recorded, except that it was noted that the first pregnancy had resulted in a miscarriage at three months and that the next four babies were all delivered normally but died in infancy.

Physical examination on entrance showed a patient who was apparently not seriously ill. The breasts were lactating. The heart was essentially normal. There were a few rales in the bases of the lungs. The lower quadrants of the abdomen were spastic and tender. The uterus was in the midline, extended half the distance to the umbilicus and was very tender. Bilateral costovertebral tenderness was present.

A Wassermann test was negative. The blood showed a white-cell count of 14,800 and the urine contained many pus cells. A blood culture showed the presence of *Staphylococcus albus*.

The treatment was essentially conservative. The patient was given rectal fluids, the bladder was irrigated, and hot douches were administered. Her condition became progressively worse, and on the day following entry she was irrational. She died on July 21, one week after admission.

Comment. This is another case of a normal delivery which resulted in fatal puerperal sepsis. It is possible that in spite of the history there was fever before the tenth day. In cases in which the infection does not begin until the tenth day a fatal outcome is most unusual, except for those involved in a hospital epidemic, when the infection may start almost any time during convalescence.

The uterus was left entirely alone, but in spite of conservatism, the infection was overwhelming. Whether or not *Staphylococcus albus* was the etiologic agent was unproved, its recovery from a blood culture usually indicates contamination. The efficacy of the douches is open to question. They may do some good in low grade parametric infections, but there can be no rationale for their use in cases of general sepsis.

DEATHS

CRANDON—LE ROI G. CRANDON, M.D., of Boston, died December 27. He was in his sixty-seventh year. Born in Chelsea, he attended the Chelsea High School and Harvard University. He received his degree from the Harvard Medical School in 1898. Dr. Crandon was a house officer at the Boston City Hospital for two years and then began the practice of surgery. He was visiting surgeon at the Boston City Hospital from 1903 to

1918, assistant in surgery at the Harvard Medical School from 1904 to 1917 and secretary of the Suffolk District Medical Society from 1903 to 1908.

In 1917 Dr. Crandon organized Naval Station Hospital Unit No. 9 and entered the navy with the rank of lieutenant-commander, serving until 1919.

Dr. Crandon was a fellow of the Massachusetts Medical Society, the American Medical Association and the American College of Surgeons.

His widow survives him.

HALL—JOSIAH N. HALL, M.D., of Denver, Colorado, died December 20. He was in his eighty-first year.

Born in North Chelsea, he received his degree from Harvard Medical School in 1882. Before moving to Colorado, he served as house physician at the Boston City Hospital for eighteen months. He practiced in Colorado for fifty-four years. At the time of his death, he was professor of medicine, emeritus, at the University of Colorado School of Medicine. He was also a past president of the Colorado State Board of Medical Examiners and the Colorado State Board of Health and had served as a physician for the city and county of Denver.

Dr. Hall was a former member of the Massachusetts Medical Society and was a fellow of the American Medical Association, the American College of Physicians and the American Clinical and Climatological Association.

JACOBS—HENRY B. JACOBS, M.D., of Baltimore, Maryland, died December 20. He was in his eighty-second year.

Dr. Jacobs was born in Scituate and attended Harvard University. He received his degree from Harvard Medical School in 1887 and interned at the Massachusetts General Hospital. He joined the staff of the Johns Hopkins Hospital in Baltimore, where he became an authority on tuberculosis.

Dr. Jacobs was a former member of the Massachusetts Medical Society and was a fellow of the American Medical Association.

CORRESPONDENCE

SUGGESTION FOR A NEW COMMITTEE

To the Editor. The communication published in the December 7 issue of the *Journal* from Medical and Surgical Associates, suggests the possible development in Massachusetts of prepaid medical care furnished by group medical practice. It is to be expected that after and possibly during an experimental period, should this method appear to the public sound and desirable, such groups will multiply and render service in a variety of ways.

If and when such types of contract medicine increase and multiply the greatest danger—both to the public and to the profession—will be from inadequate personnel and poor service. In the past, some forms of contract medicine have resulted in a deterioration of medical service. It is of interest to organized medicine and to the public that this should not happen in the future. In helping to avoid this danger and at the same time in permitting experimental solution of the economic and medical problems involved lies a great opportunity of organized medicine to be of service to the public. Within organized medicine is to be found the only group of experts who can properly appraise the quality of medical care provided by group medical practice and effectively pass judgment on such practice for the purpose of maintaining and improving the standards of medical care.

I therefore suggest that the Massachusetts Medical Society might wisely set up a committee charged with the duty to study the quality of medical care which such groups give and to report its findings to the Society. It seems probable that it would be wise to set up for this purpose a new committee, since the work might well become burdensome and be somewhat different from that of any of the present existing committees. This committee should be composed of men steeped in the wisdoms of clinical medicine, but it might also wisely include physicians primarily concerned with the fundamental sciences and with hospital administration.

Such a committee representing the Massachusetts Medical Society, which has long held a high position in the public regard, might have a tremendous influence not only in collecting facts upon which the official opinions of the Society might be based, but in influencing public opinion through which, in the last analysis, the medical profession can most certainly influence social changes.

REGINALD FITZ

Boston

A RECOMMENDATION

To the Editor I recently saw the motion picture, "Disputed Passage." I want to recommend it to those physicians who have organized to distribute medical services on the combined insurance and chain store plan. I should also recommend it to those physicians who contemplate selling their services to the Medical and Surgical Associates, for resale through Health Service, Incorporated, to the individual.

The picture is not on the theme of socialized medicine or the chain store type of distributing medical services, but it points a moral that should be instructive to those working to separate the general practitioner from his patient.

JOHN F. CASEY, M.D.

475 Commonwealth Avenue,
Boston

REPORTS OF MEETINGS

HARVARD MEDICAL SOCIETY

A regular meeting of the Harvard Medical Society was held at the Peter Bent Brigham Hospital on October 24, with Dr. Soma Weiss presiding.

As an introduction two cases of jaundice were presented. The first of these was that of a forty-nine-year-old man who had showed almost complete lack of bile pigments in the stools since the beginning of his jaundice three weeks before entry. The diagnosis had not been definitely established but lay between catarrhal jaundice and pancreatic carcinoma. The second case was that of a thirty-nine-year-old woman who had had a cholecystectomy for stones in May, 1939. At that time the common duct was explored and said to be normal, fifteen days postoperatively bile had drained through the wound. Since operation she had had several attacks of pain in the right upper quadrant, one of which was associated with jaundice and itching. The diagnosis on this admission was thought to be common-duct stone.

Dr. Otto Schales, the principal speaker of the evening, was then introduced. His topic was "Pseudohemoglobin and Related Compounds in Health and Disease."

After a few preliminary remarks on the structure and chemical reactions of hemoglobin and an enumeration of other iron-containing physiological substances, Dr. Schales discussed the properties of pseudohemoglobin.

When normal blood is treated with dilute hydrochloric acid, ionized iron is liberated in constant amounts (about 15 mg per liter of blood). It has been shown that this iron is not derived from hemoglobin but from related compounds, "E" and "E₁" which occur in the red blood cells.

It has been shown that compound "E" reacts with carbon monoxide and that its relative carbon monoxide affinity is about ten times greater than that of hemoglobin. In combination with carbon monoxide, compound "E" will not liberate ionized iron when treated with dilute hydrochloric acid. This fact has been utilized in testing for low concentrations of carbon monoxide in the blood, since the carbon monoxide combines first with compound "E" and later with hemoglobin. Even when spectroscopic examination of a blood suspected of containing carbon monoxide fails to reveal the presence of carboxyhemoglobin, treatment of the blood with dilute hydrochloric acid will fail to release ferrous ion in normal amounts when even very small quantities of the gas are present. As the patient recovers from his exposure to the gas, the ionized iron obtainable rises to a normal value.

Chemical studies have shown that compound "E" contains a pseudohemin in which the porphyrin ring, which is closed in hemoglobin, is open. Compound "E" has been called alpha pseudohemoglobin to denote this relation. Alpha pseudohemoglobin will react with carbon monoxide as related above, but not with cyanides. It can be converted to a related compound in which the iron contained within the molecule is in the ferric state—a substance analogous to methemoglobin—and which normally represents about one third of the "easily split off" iron in blood. This substance is known as alpha pseudomethemoglobin or compound "E₁", it reacts with cyanides but not with carbon monoxide. The other reactions of alpha pseudohemoglobin and alpha pseudomethemoglobin are similar to their related compounds, hemoglobin and methemoglobin, with which they are identical so far as the protein (globin) as bearer of the prosthetic groups is concerned.

Hemoglobin may be converted into alpha pseudohemoglobin by means of hydrogen peroxide in presence of potassium cyanide and also by certain reducing agents in presence of oxygen. Perhaps the ascorbic acid in the blood, acting by producing nascent hydrogen peroxide, is responsible for the normal breakdown of hemoglobin into bile pigment by this route, with pseudohemoglobin and pseudomethemoglobin as intermediate products of bilirubin formation. Since hydrogen sulfide produces hydrogen peroxide in the presence of oxygen, sulfhemoglobin may be closely related to the pseudohemoglobins.

Little is known about the blood level of pseudohemoglobins in pathologic conditions. It is about half normal in pregnancy, carcinomatosis and habitual tobacco smokers. It is three-quarters normal in cases of general paresis following malaria treatment and less than half normal in lead poisoning. These values are independent of the blood hemoglobin levels.

Dr. Schales demonstrated his method of detecting hydrogen peroxide in dilutions as high as 1:100,000,000. In alkaline solution with mesohemin and Luminal present, hydrogen peroxide gives a brilliant luminescent light which is quite striking.

Dr. E. J. Cohn in discussing the paper suggested that the study of pseudohemoglobins might be of great im-

portance because changes related to them appear before changes related to hemoglobin and in spite of compensatory mechanisms which keep hemoglobin normal.

Dr Arnold P. Meiklejohn pointed out the fact that the previous theory was that hemoglobin was broken down normally by conversion into porphyrin. If it is true that hemoglobin is converted normally into pseudohemoglobin by breakage of the porphyrin ring then the presence of porphyrin in the urine takes on a pathological significance hitherto unappreciated.

NOTICES

CARNEY HOSPITAL

The monthly clinical meeting and luncheon of the Carney Hospital will be held on Monday, January 15 at 11:30 a.m.

PROGRAM

Case Reports

Femoral embolectomy

Habitual abortion.

Subacute bacterial endocarditis.

Physicians and medical students are cordially invited to attend.

ROY J. HEFFERNAM M.D., *Secretary*

BOSTON CITY HOSPITAL

Dr Oscar Hirsch formerly professor of laryngology at the University of Vienna will give a lecture on "Tumors of the Pituitary Body" on Thursday, January 18 at 11:00 a.m., in the Cheever amphitheater.

The medical profession is cordially invited to attend.

PETER BENT BRIGHAM HOSPITAL

A joint medical and surgical clinic at the Peter Bent Brigham Hospital will be held on Wednesday, January 17, from 2 to 4 p.m. Drs. W. T. Green and E. A. Stead will speak on "Painful Feet." A clinicopathological conference conducted by Dr. E. C. Outler will take place from 4 to 5 p.m.

On Thursday, January 18 from 8:30 to 9:30 a.m. there will be at the Children's Hospital, a combined clinic, conducted by Dr. K. D. Blackfan of the medical, surgical, orthopedic and pediatric services of the Children's Hospital and the Peter Bent Brigham Hospital.

Physicians and students are cordially invited to attend.

BOSTON MEDICAL HISTORY CLUB

There will be a meeting of the Boston Medical History Club at the Boston Medical Library, 8 Fenway Boston on Monday evening January 15 at 8:15. Dr. Fuller Albright will talk on "Hyperparathyroidism."

All those interested in the subject are cordially invited to attend.

PAUL D. WHITE, M.D., *President*
BENJAMIN SPECTOR M.D., *Secretary*

BOSTON LYING-IN HOSPITAL

Dr. George V. Smith will speak on "Hormonological Aspects of the Toxemias of Pregnancy" before the Journal Club at the Boston Lying-in Hospital, on Tuesday evening, January 23 at 8:15.

FREE PUBLIC LECTURES

The Quincy City Hospital in conjunction with the Social Service Committee, is offering a course of free

health lectures, to be given in the Administration Building of the Hospital at 3:00 p.m. on Sundays. The schedule is as follows:

- January 14 Prevention and Control of Disease. Dr. Charles F. Wilensky
- January 21 Heart Disease. Dr. Arthur Rapoport.
- January 28 Planning the Family Menu for Better Health with Consideration to the Budget. Miss Marion D. Floy
- February 4 Food and Its Influence on the Teeth. Miss Ruth L. White.
- February 11 Mental Health for the Adult. Dr. Arthur Berk.
- February 18 Headaches Causes and treatment. Dr. Alfred V. Mahoney
- February 25 Diet During Infancy and Childhood. Dr. Edmund B. Fitzgerald and Miss Anne Morin.
- March 3 Diseases of the Skin. Dr. Francis P. McCarthy
- Hygiene of the Skin. Miss Margaret G. Reilly
- March 10 Sulfanilamide and Sulfapyridine. Dr. Burton Elder

HAMPDEN DISTRICT MEDICAL SOCIETY

The regular winter meeting of the Hampden District Medical Society will be held in the rooms of the Springfield Academy of Medicine, 20 Maple Street, Springfield on Tuesday January 23 at 4:00 p.m.

Dr. Chester M. Jones will speak on "Substernal Pain a Confusing Symptom Its clinical significance. Discussion will follow.

Supper will be served at 6:00 p.m.

WAYNE C. BARNES *Secretary*

NORFOLK DISTRICT MEDICAL SOCIETY

The next meeting of the Norfolk District Medical Society will be held in the auditorium of the Norwood Civic Center Tuesday January 30, at 8:30 p.m. The meeting will be under the auspices of the staff of the Norwood Hospital. The Civic Center is adjacent to the hospital.

PROGRAM

Business Reports from committees.

Communications Papers by the Norwood Hospital staff.

Discussion.

Collation.

FRANK S. CRUICKSHANK, M.D., *Secretary*

LEWIS CASS LEDYARD JR., FELLOWSHIP

The Lewis Cass Ledyard Jr., Fellowship was established in 1939 by a gift from Mrs. Ruth E. Ledyard, wife of the late Lewis Cass Ledyard Jr., a governor of the New York Hospital. The income, amounting to approximately \$4000 annually will be awarded to an investigator in the fields of medicine and surgery or in any closely related field. This amount will be applied as follows: \$3000 as a stipend and, approximately \$1000 for supplies or expenses of the research. In making the award, preference will be given to young applicants who are graduates in medicine, and who have demonstrated fitness to carry on original research of high order. The recipient of this fellowship will be required to submit reports of his work under the fellowship either at stated intervals or at the end of the academic year and when the result of his work is published he will be expected to give proper credit to the Lewis Cass Ledyard Jr., Fellowship. The research work under this fellowship is to be carried on at the New York Hospital.

and Cornell University Medical College. The fellowship will be available on July 1 at the beginning of the academic year. Applications for the year 1940-41 should be in the hands of the committee by February 15. It is expected that the award will be made by April 1.

Application for this fellowship should be addressed to Committee of the Lewis Cass Ledyard, Jr., Fellowship, The Society of The New York Hospital, 525 East 68th Street, New York City.

SOCIETY MEETINGS AND CONFERENCES

CALENDAR OF BOSTON DISTRICT FOR THE WEEK BEGINNING MONDAY, JANUARY 15

MONDAY JANUARY 15

- *11 30 a.m. Monthly clinical meeting Carney Hospital
- *12 15-1 15 p.m. Clinicopathological conference Dr S Burt Wolbach Peter Bent Brigham Hospital amphitheater
- 5 p.m. Cutter Lecture Harvard Medical School Amphitheater E.
- *8 15 p.m. Boston Medical History Club Boston Medical Library 8 Fenway

TUESDAY JANUARY 16

- 9-10 a.m. Nephritic Clinic Presentation of cases Dr R W Buck Joseph H Pratt Diagnostic Hospital
- 10 a.m.-12 30 p.m. Boston Dispensary tumor clinic
- 12 m. South End Medical Club Headquarters of the Boston Tuberculosis Association 554 Columbus Avenue Boston
- 12 15-1 15 p.m. X ray conference Dr Merrill C Sosman Peter Bent Brigham Hospital amphitheater

WEDNESDAY JANUARY 17

- 9-10 a.m. Hospital case presentation Dr S J Thannhauser Joseph H Pratt Diagnostic Hospital
- *12 m. Clinicopathological conference Children's Hospital amphitheater
- *2-4 p.m. Joint medical and surgical clinic Peter Bent Brigham Hospital

THURSDAY JANUARY 18

- *8 30-9 30 a.m. Combined clinic of the medical surgical orthopedic and pediatric services of the Children's Hospital and the Peter Bent Brigham Hospital at the Children's Hospital
- 9-10 a.m. Surgical case clinicopathological presentation Dr H F Day Joseph H Pratt Diagnostic Hospital
- 11 a.m. Tumors of the Pituitary Body Dr Oscar Hirsch Boston City Hospital

FRIDAY JANUARY 19

- 9-10 a.m. A Discussion of Rheumatic Fever Dr T Duckett Jones Joseph H Pratt Diagnostic Hospital
- 10 a.m.-12 30 p.m. Boston Dispensary tumor clinic
- *1 p.m. Urological conference at the Massachusetts General Hospital lower amphitheater Out Patient Department
- *12 m. Clinical meeting of the Children's Medical Service Massachusetts General Hospital Ether Dome

SATURDAY JANUARY 20

- 9-10 a.m. Hospital case presentation Dr S J Thannhauser Joseph H Pratt Diagnostic Hospital
- *10 a.m.-12 m. Medical staff rounds of the Peter Bent Brigham Hospital Conducted by Dr Soma Weiss

SUNDAY JANUARY 21

- 4 p.m. What about Sulfanilamide? Dr Chester S Keefer Free public lecture. Harvard Medical School amphitheater of Building D

NUMBER 3

THE TREATMENT OF PILONIDAL SINUS IN HOSPITAL PRACTICE*

HORATIO ROGERS, M.D.†

BOSTON

THE lesion commonly known as pilonidal sinus offers to the embryologist an interesting subject for speculation, but to the surgeon it presents essentially the problem of making a wound heal in a place where it does not want to heal. The suggestions for curing this trouble some lesion are many and ingenious, but as elsewhere in medicine the very multiplicity of remedies is evidence that not one is entirely satisfactory.

Patients will be cured and will fail to be cured by all the methods of treatment described in the literature, and some of the cures will be brilliant and some of the failures will be most distressing. The average surgeon who is called upon to treat an occasional case finds it difficult to evaluate the usefulness of various methods and is inclined to stick to the one with which he is familiar. The same is true in hospital practice where the changing personnel of the resident staff permits of no evaluation of methods so that the same traditional method is likely to be passed along for years regardless of the end result.

At the Massachusetts General Hospital our failures have been reduced from about 30 per cent to the neighborhood of 3 per cent since 1932, when a special study of this disease was undertaken and it is now believed that an account of our experience may be of sufficient interest to warrant a brief presentation.

Prior to 1932, all cases of pilonidal sinus were operated on in the hospital, and followed in the Out Patient Department, so that some of our poor results could be ascribed to the division of responsibility between the surgeon who did the operation and the various surgeons who carried out the aftercare. We have now simplified the operation to the status of an outpatient procedure and have largely eliminated this division of responsibility.

In 1932 an analysis and follow up of the cases

of 119 patients treated during the eight preceding years showed that 30 per cent had not been cured of their disease.¹ These patients had all been operated on under general or spinal anesthesia. In most cases an attempt had been made to outline the extent of the sinus by the injection of methylene blue into the main opening. Radical excision had then been done of a block of skin and fat large enough to ensure the removal of all diseased tissue. Frequently the coccyx and sacral periosteum had been removed when found stained by dye. The wounds were often very large. Some of the wounds had been closed, with or without drainage, by undercutting, by plastic flaps and by deep stay sutures in an effort to eliminate dead space. The rest had been packed wide open with gauze. The average postoperative hospital stay had been eleven days. In the cases which were cured the average time of wound healing had been about three months and many of the resultant scars were large unsightly and uncomfortable.

On the basis of this investigation it was apparent that many of our difficulties were directly related to the large size of the wounds. We are now convinced that except in rare cases such large wounds are entirely unnecessary and that the morphological conception on which they were based is fallacious.

In order to reach this conclusion it was necessary to undertake a pathological study of a number of surgical specimens from representative cases. Therefore, between 1932 and 1934, 72 additional radical excisions were done, primarily with the purpose of securing pathologic material for study, but also for the opportunity of making careful clinical observations on a controlled series of cases. About half the operations were done by me personally, and the rest were performed under my close supervision, but in spite of scrupulous attention to the choice of procedure and details of technique our results were not

*Read at the annual meeting of the New England Surgical Society, Salem, September 29, 1939.

†Assistant in surgery Harvard Medical School; assistant surgeon Massachusetts General Hospital.

improved in any respect over those of previous years

Meanwhile a painstaking examination of the surgical specimens was being carried out by Dr Marshall G Hall of the Pathological Department, and his study revealed four facts of the greatest practical importance³

First, with regard to morphology, over 70 per cent of the sinus tracts were simple midline structures which could have been included in a piece of tissue 2 by 2 by 5 cm

Second, the coloring matter which had been injected during life, and which was interpreted at operation as indicating fine ramifications of the sinus tract, was seen on microscopic examination to be filling lymphatic trunks in perfectly normal tissues

Third, infection was found to be present in every case, and the only changes seen to have taken place were those caused by infection. There was no evidence that the epithelial rests constituting the original congenital defect had any tendency to extend except as they were forcibly displaced by abscess and scar-tissue formation

Fourth, the almost universal belief that recurrent sinuses after surgical excision were always due to incomplete removal of epithelial tissue was disproved by demonstrating its absence in a number of specimens from recurrent cases. Furthermore, the cause of these recurrences was shown to have been infected dead space and nothing else

All these findings led to the conclusion that large radical excisions are unnecessary and that the problem is chiefly one of wound healing in the presence of infection. It remained to apply these ideas to the actual treatment of patients. In 1935 we began the conservative excision of pilonidal sinuses in the Out Patient Department⁴. The tissues were locally infiltrated with novocain containing adrenalin, and the sinus tract and hair nest were dissected out through a midline skin incision in a nearly bloodless field by means of a small cautery blade. The resultant narrow wound was then packed with gauze, and the patient was allowed to go home. In most cases this proved to be a minor procedure requiring from twenty to thirty minutes and causing the patient no more reaction than does the excision of a wen. Several patients returned to their work or attended a ball game or a dance on the day of operation. We soon discovered, however, as was to be expected, that the occasional patient with a lesion complicated by extensive scarring was best managed in the hospital under a general anesthetic. Of the 150 cautery excisions done between 1935 and 1937, 14 were done in the hospital and 136 in the Out Patient Department

All the wounds were left open because we believed them all to be infected, and because the natural way for infected wounds to heal is by second intention. The patients returned Mondays and Thursdays to have their dressings done by the surgeon who operated on them, and each surgeon exerted himself to have his patients heal the fastest of any. The shortest healing time in this series was five weeks, but more recently it has been reduced to four weeks. Except for certain cases of definitely delayed healing, the average time was about nine weeks. The wounds healed to a soft, inconspicuous linear scar.

The fact that 97 per cent of these patients were cured by a conservative excision and have stayed cured for one to four years convinces me that large block excisions of tissue carried out under the deceptive guidance of injected coloring matter are neither necessary nor desirable. This belief is apparently gaining ground, at least locally, since 70 additional cautery excisions have been done at the Massachusetts General Hospital in the past year and a half by the resident staff and by seventeen different members of the visiting staff, as compared with only 8 radical block excisions.

The establishment of this principle simplifies the treatment of pilonidal sinus, but it falls far short of solving its problems. There will always be a small proportion of troublesome cases which will be hard to cure by any method. All pilonidal sinuses have something in common: they originate in the midline and are infected, but beyond that they may show every variation from the simplest to the most complex. Therefore we must recognize that they cannot all be treated alike. Our experience has been that in hospital practice the procedure of conservative cautery excision and healing by second intention comes within the reach of more patients and gives better results than any other method we have tried, and if a single method of treatment must be adopted as a routine, this is probably the best one at the present time.

Although this paper is primarily concerned with the treatment of hospital patients it applies, with certain modifications, to private patients as well. I have done a number of cautery excisions in my office without encountering trouble, but because of the uncertainty of knowing in advance just how extensive the excision may need to be, I prefer to do such excisions in the hospital. The situation is a little different in an outpatient department, where a patient may be kept overnight in the emergency ward if it seems desirable. Furthermore, most private patients themselves prefer to be in the hospital where they can be waited on for a day or two afterward. And there is

nothing to be gained by avoiding hospitalization, since the question of divided responsibility does not arise.

Perhaps the most important reason for hospitalizing the private patient, however, is the chance it gives for varying the operative procedure in accordance with the actual findings. The use of the cautery is not essential in doing a successful conservative excision, it simply facilitates it by providing an almost bloodless field. The same thing can be done by careful sharp dissection and the use of a little more adrenalin in the novocain and if the defect is small and not too badly infected to interfere with primary healing, it may be sutured by some one of the technics described in the recent literature, with a reasonable chance of cure.

CONCLUSION

A six years experience in the treatment of pilonidal sinus at the Massachusetts General Hospital has convinced me that most failures are not due to incomplete excision of diseased tissue but to faulty wound healing caused by infection and retained dead space, that there is no practical or theoretical justification for the radical excision of large blocks of normal skin and subcutaneous tissue, and that in unselected cases the highest percentage of cures can be obtained by conservative excision of the sinus tract and hair nest under direct vision, followed by solid second intention healing of the open wound, with the patient ambulatory and under the care of the same surgeon from first to last.

DISCUSSION

DR. WALFORD T. REES, Burlington, Vermont: Dr. Rogers has given us all something to think about. I have had no experience with the use of cautery excision of pilonidal sinus. I have had some little experience with other methods of treatment and most of it has been rather disappointing. I looked up our records at the Mary Fletcher Hospital during the past ten years. There were 35 cases of pilonidal sinus which had been taken care of by several operators. I attempted to follow up the records of these cases, but was unsuccessful except for my own cases, which numbered 15. Thirteen were operated on by block dissection and some method of flap repair. There were 5 recurrences among the 13 cases, or 38 per cent, which is, of course, too much. Two cases operated on by block excision and then packed wide open had no recurrence.

Now if Dr. Rogers, by his method, can show us only 3 per cent recurrences, it is probably the method for all of us to use. He says that it should be done by one surgeon

familiar with the operation and my experience, particularly with the aftercare leads me to subscribe to that.

I agree heartily with Dr. Rogers that most of our recurrences are due not to the fact that some sinus was left at the time of the original operation but to neglect in the care of the wound. This is very important, because, I believe, this condition happens most frequently in hairy individuals, and if at the time of dressing we are not careful to shave the surrounding skin and prevent the edges of the wound from invaginating we shall get recurrences.

The flap operation in certain cases has a great deal to recommend it. If you can send a patient into the hospital remove a sinus and do a flap operation, covering over the lower end of the scarum, the patient can be discharged from the hospital in from five to seven days, and if there is no infection the patient does not have to have dressings for six to nine months. This method has a great deal to recommend it, and I am sure that the patient who receives this type of operation likes it better than having to have dressings for a long time. Unfortunately we get a high percentage of recurrences.

Possibly early cases of pilonidal sinus which have not been the seat of frequent infections abscess formation and accessory sinuses may still be treated by the flap method. Probably in the majority of cases that have had frequent bouts of infection multiple sinus formations are best treated by excision, either by the cautery as described by Dr. Rogers or by wide-open packing with careful, frequent dressings.

DR. CARL H. STEVENS, Belfast Maine: In reviewing the literature, I find that several methods of treatment for this relatively rare condition have been advocated. The sclerosing method seems to have been discarded. Excision with primary union seems to be indicated in uninfected cases, but as most of the cases when seen are already infected to attempt to obtain primary union seems rather unwise. Therefore the method most highly favored is excision and wide excision.

Until Dr. Rogers developed his method it seems that excision by the knife, using a wide elliptical incision down to the fascia was the method of choice, but I think that he has shown definitely that the use of the electric cautery has a distinct advantage, as it reduces both the time required to obtain a permanent cure and the rate of recurrence.

DR. FRANK H. LAHEY, Boston: Inasmuch as we have published a method of treating these cases radically, it becomes my duty to say that since Dr. Rogers has developed this method we have treated almost none by the radical method. His method is the one we have taken up and applied, and we have had just the same degree of satisfaction that he has had. I think it is a real advance.

DR. DANIEL C. PATTERSON, Bridgeport, Connecticut: We have all had the experience with pilonidal sinuses of trying various methods to close them and to get primary union, but with infrequent success. We have excised the sinuses and packed the cavity with gauze. This method of healing by granulation has given good results, but entails a long period of dressing which is not very pleasant.

Dr. Rogers's procedure is without doubt the best universal method to be carried out when the operations are done in the outpatient department or by the resident staff, and also in badly infected cases; however, there are some cases I am sure, in which clean, early healing can be secured and the patient saved the inconvenience of months of dressing. Doubtless every surgeon has treated cases in which he had suspected that the sinus could probably be closed.

In such cases I have of late tried the following procedure, and in the few so far operated on have had most satisfactory results. The sinus and cyst are injected without force with a weak solution of methylene blue, and excised, care being taken not to remove too big an area of normal skin, bleeding is controlled and the cavity is closed up to the skin with fine chromic gut. No sutures are placed through the skin. I have assumed that if suppuration did occur it would work toward the surface, and not meeting the resistance of a skin sutured wound would cause but little trouble.

Whether or not the patients so treated will have trouble later on is of course yet to be discovered. I think that the procedure is worth trying in many cases, as the technic is so simple.

DR PETER P CHASE, Providence, Rhode Island. In July, 1938, I operated on a big, fat girl with pilonidal sinus, and the wound apparently healed at once. In May of this year I was much distressed to find a large abscess. I had to open it and found a cup or two of pus. The patient went away for the summer, but this fall she said that she still had a weeping sinus. Can I go ahead with the cautery and do as Dr Rogers has said and expect to get a perfect result?

DR PHILEMON E. TRUESDALE, Fall River, Massachusetts. Dr Lahey is always about two laps ahead of me, but I still stick to the radical operation because I think it does remove all the sinuses, and you only have to operate once.

DR JOHN HOMANS, Boston. In operating on this condition, I split the sinus and remove it with a heated instrument, but I believe it is possible to close the deeper part of the wound and leave the top part open, probably with less delay in healing.

DR ROGERS (closing). Dr Rees perhaps misunderstood me as meaning that only one surgeon should ever operate on pilonidal sinuses, and that it should become a specialty. I meant that each patient with a pilonidal sinus should be under the care of the same surgeon until cured. It was only for this reason that we believed it necessary to make the entire management an outpatient procedure.

Dr Stevens referred to the rarity of the disease. I think that it is for that reason that so many men who know far more about more important lesions are unable to evaluate the different methods which are described for managing this one.

As to lateral extensions, if the sinus opening is more than 3 cm from the midline, a right angle skin incision must be made out to it and 0.5 cm. beyond it. If it is closer to the midline, it is a simple matter to undercut

the skin to beyond the extreme lateral extent of the abscess wall.

Dr Patterson spoke of partial closure. We have had experience with partial closure of different kinds, and have abandoned it because we believe that the recurrence or failure is due essentially to what may be called a soft tissue sequestrum hidden in the wound. The type of abscess that Dr Patterson mentioned is commonly seen after partial or complete primary closures in which, owing to dead space, second intention healing is allowed to take place out of sight. I have watched cases of that sort in an open wound and have seen a place where the blood supply was apparently inadequate to support normal granulation tissue become farther and farther depressed below the level of the actively growing granulation, and finally have seen the active granulation close in over it and make a little vacuole with chronically infected granulation tissue walls. The wound then continued to heal up to the top, and the scar healed across it, hiding the infected dead space from sight. Weeks or months later the abscess came and the recurrent sinus developed. Such a sequence can be prevented in an open wound. In a closed or semiclosed wound it accounts for many failures.

The recurrent case of Dr Chase can be operated on by this technic exactly as the primary case can be, but in the presence of extensive scar tissue it is impossible to get adequate anesthesia with novocain, and a general anesthetic has to be used.

If our experience had been the same as Dr Truesdale's, namely that only one operation is necessary provided it is radical enough, I should perhaps favor doing the radical operation. But I have not found that to be true. Our failures following radical excision amounted to 18 per cent even when the wounds were packed wide open. Disregarding the way the wounds were handled, radical excision resulted in failure for 50 of the 140 patients in our earlier series.

In closing, I do not mean to leave the impression that cautery excision is the only way in which pilonidal sinuses can be cured. By a proper selection of cases, some of them can be excised cleanly enough and closed right off by some of the methods described, with a fair expectation of cure. I do not believe that this can be successfully done in a general hospital clinic, and I suspect that any surgeon who attempts it in private practice is risking the loss of more than he stands to gain if successful. If he succeeds, he is excused from a number of dressings and the scar will not be any better, but if he fails, he has the whole thing to do over again and possibly more than once. Nevertheless, and subject to those limitations, I think that there is a place for some of the various methods that have been described for primary closure of these wounds.

PRESIDENT'S ADDRESS*

CLARENCE O COBURN, M.D.†

MANCHESTER, NEW HAMPSHIRE

DURING the past year, I have had the honor of serving this society as its one hundred and forty-seventh president. The task has not been too arduous, and I feel more than recompensed for the effort I have expended. The visits to the several county societies have been especially pleasant. Here I have had the opportunity not only to meet many old friends, but also to get acquainted with many physicians whom I had not previously known, and have been privileged to listen to their scientific papers and to enter into their discussions. I never come away from one of these meetings without a deeper appreciation of the value of the work being done by the members of our society, and I especially urge all members to attend these meetings each spring and fall. In these small groups—component parts of the New Hampshire Medical Society—one and all may express their views, ask questions or discuss any topic that may interest them, with less formality than in a large meeting such as that we are attending today.

In two years, the New Hampshire Medical Society will celebrate its one hundred and fiftieth anniversary, and at that time I hope the officers and committees will make every effort to have this a gala occasion.

Many changes in the practice of the healing art have taken place since the Society was founded. Advances have constantly been made in all its branches. New instruments and apparatus have been developed to make diagnoses more exact. New drugs, surgical procedures and other forms of therapy have made possible more rapid and successful recoveries. During this time of phenomenal scientific advancement, we have been prone to ignore the social and economic side of the practice of medicine, and we are now confronted with what we regard as a radical change in and a challenge to our rights as practicing physicians. For years the State has increasingly assumed the care and treatment of various diseases and conditions which were formerly the problems of the individual physician. All doctors will agree that there are certain conditions affecting the public welfare which can be treated more effectively as a state project. Especially is this true of certain mental conditions, of the control and prevention

of contagious diseases, of the infirmities which may eventually make the individual a public charge, of sanitation and of any condition affecting the public health. All these have necessitated the formation of many agencies, the establishment of a number of institutions and the expenditure of large sums of money for their maintenance. This has actually put the State into the practice of medicine. While all this has no doubt been necessary and inevitable, I, for one, did not appreciate the magnitude of the work or understand the functions of the several agencies until as your president I visited the institutions and talked to the heads of the many departments. As it will probably be impossible for each one of you to become familiar with these organizations and to visit the institutions, perhaps my impressions and findings will be of value to you.

THE STATE HOSPITAL

The largest of our institutions is the New Hampshire State Hospital at Concord which opened its doors in October, 1842, with facilities for 96 patients. Today there are fifteen buildings with a total of forty-eight wards, the maximum desirable capacity of which is 1565 but there are actually 2219 patients, or, an overload of more than 600. The greatest appreciable increase was between the years 1903 and 1914 during which period the mentally ill patients who were being cared for at the different county institutions were transferred to the State Hospital. However, this increase in population has continued at about the same rate to the present date, owing to a number of causes. There was a time when these patients could be cared for in their homes or in private institutions, but economic conditions have necessitated their depending more and more on the State. Another contributing factor is that the general public has become hospital-conscious, and realizes that the hospital is a place for the treatment and cure of the mentally ill rather than just a place of retention for these unfortunates, so today it is the exception rather than the rule that these patients are treated at home. The New Hampshire State Hospital Survey of 1938, made by the State Planning and Development Commission, states that the hospital has two functions—to cure and improve the mental illnesses of the State's citizens and to act as a place

*An address read at the annual meeting of the New Hampshire Medical Society, Manchester, June 9, 1939.
†President, New Hampshire Medical Society.

of custody for those citizens who cannot be cured or improved

Keeping pace with this increase in hospital population has been a corresponding increase in the efficacy of the management and treatment. The hospital has a very efficient staff of specialists who employ all the modern equipment and therapeutic procedures. The death rate has decreased from 115 per 1000 in 1919 to about 60 in 1938.

The largest number of admissions are by certification of physicians, but there are also many voluntary ones, and some by court order. We are very fortunate in New Hampshire in being able to commit a patient on the certification of two physicians, whereas in some states an order of the court is required. This permits the earlier treatment which is essential in many cases to effect a cure. In making out certificates of commitment, physicians should give as clear a picture of the case as possible, fully answering all questions on the blank, and seeing that it is properly signed and sworn to, before sending a patient to the hospital. I am informed that in the past much inconvenience and considerable delay have been caused by the incompleteness of these legal forms.

I was considerably impressed by the manner in which the newly admitted cases are handled. They are placed in the admission ward, when possible, where they are studied by the staff, and after frequent consultations are placed in suitable surroundings and given the care required for their individual conditions. The staff is always willing to have, and welcomes, conferences and discussions with the committing physicians.

It can readily be seen that the present institution is much overcrowded and that additional facilities are needed to care for the overload. It has been recommended by the superintendent, Dr. Charles Dolloff, that there be some new construction at Concord and that the farm at this site be discontinued and a new farm procured at some place not more than thirty miles distant, with sufficient buildings and facilities to care for any surplus which may develop in the future.

The hospital also has other needs than that of additional room for patients. Much should be done in the prevention of mental diseases. For the last five years, through the work in the mental-hygiene clinics, a number of children have been found requiring hospitalization under psychiatric supervision. Unfortunately no hospital in the State has facilities for the care of these cases, and such a unit established at the State Hospital as a therapeutic and diagnostic center would serve an excellent purpose.

Epilepsy continues to be one of our problems.

At present these patients, if in the State Hospital, are placed on the same ward with psychotic patients. A separate unit, where they could be individually treated, would be a useful step forward.

Many patients seen in the venereal clinics suffer from neurosyphilis and would benefit from more expert therapy for this condition, including fever therapy. Unfortunately the early cases showing no mental symptoms are at a disadvantage because the patients are unable to receive treatment at the State Hospital until they are actually considered insane. It is hoped that some arrangement can be made whereby all indigent patients with neurosyphilis can receive additional treatment at the State Hospital in the early stages, when they would benefit from it most.

The extramural activities of the hospital deserve high praise and support. Clinics are now held by members of the staff in Concord, Manchester, Nashua, Dover and Portsmouth. This gives the local physicians the benefit of expert advice on their problems, and it is to be hoped that a large number of physicians will take advantage of this opportunity.

THE STATE SCHOOL

Although all physicians have long recognized that there is a difference between insanity and feeble-mindedness, no special provision was made for the care of the latter until 1903, such cases having been cared for in the county institutions and the State Hospital. Strange as it may seem, the Laconia State School was definitely instituted by a petition to the legislature from the women's clubs of the State of New Hampshire. The act creating the school was passed in May, 1901, and the school was formally opened in February, 1903. During the first year there were admitted 71 persons, all that the institution was capable of caring for at that time. The original group of farm buildings, still in use, has been added to and improved. In addition, a number of new buildings have been constructed, including dormitories, a grammar school, a service building and a new, fireproof infirmary with facilities for the care of an accumulating number of infirm and bedridden children. The infirmary also contains a laboratory, rooms for dentistry and for clinical examinations, an operating room for minor surgery and drug storage space. The present census is 621 persons, of these 436 are helpful, to a lesser or greater extent, and can do some kind of work, either in the buildings or on the farm. Also under the jurisdiction of the school are 92 persons on parole.

In the grammar school there are 150 boys and girls under specially trained teachers. Academic

instruction is seldom carried beyond the age of seventeen, but in the arts and crafts and manual training departments some of the older pupils carry on further educational training. The results obtained through the untiring efforts and patience of the superintendent and his staff with these handicapped individuals are very impressive. This is especially marked in the Manual Arts Department.

Here are more than 600 unfortunates in an institution, and probably as many more throughout the State, although no census has ever been taken and no provision made for reporting this condition. This makes one wonder whether many of the conditions with which the patients are afflicted could not have been prevented or alleviated. We as physicians recognize that mental deficiency has as a basis brain lesions of an anatomical, chemical, electrical or physiological nature, either of the immediate past or perhaps remote and due to ancestral disease. This gives us a clue to some probable preventive measures such as the better practice of obstetrics in order to prevent cerebral hemorrhage or other brain injuries, the premarital blood-test law recently enacted, which should do much to obviate congenital syphilis, and the sterilization law. A paper by Baker¹ contains the following statement:

The legal sterilizing process in New Hampshire requires forty-four days of legal procedure before an operation can be done. It requires the appointment of a guardian for the occasion by the probate court whenever a competent natural guardian is wanting, complete fourteen days service of notice and a hearing before the trustees or commissioners. This law has three outstanding requirements:

1. Legal sterilizing operations can be done only on inmates of state and county institutions.
2. The person subject to a legal sterilizing operation must be insane, feeble-minded or epileptic.
3. In the words of the law the person must be found to be "a probable, potential parent of socially inadequate offspring likewise afflicted."

These measures, together with the newer methods of placing and treating babies and young children, will no doubt do much to lessen the number of these cases in the future.

SANATORIUMS

Throughout the years, physicians have led the way and pleaded for adequate sanatorium treatment for tuberculous patients in New Hampshire. None know better than they that the cost of treating this disease is high—far beyond the means of the average family—and that a considerable period of time is required in order to effect a cure. We have two sanatoriums in New

Hampshire—one state-owned and operated, at Glencliff, and the other private, at Pembroke.

The Glencliff Sanatorium is 1650 feet above sea level, the legislative act having required that the institution be established at not less than this altitude, since many specialists at that time believed that high altitude had a favorable tendency toward the cure of the disease. The institution originally consisted of an administration building and two cottage wards for patients. Both these wards were open to the south as fresh air was also considered of great importance in the cure of the disease. Thirty beds were available for patients.

Since the opening of the Glencliff Sanatorium in 1909, the growth and development of the establishment have been phenomenal. At the present time it is rated as one of the leading institutions of its kind in the country. Additions to the cottage wards have been made, so that the excessive amount of fresh air has been mitigated as is especially necessary in the extreme cold of a New Hampshire winter in the "North Country." An infirmary building with individual rooms for patients more in keeping with modern methods of treatment of the disease, was added in 1935, and several years ago an addition increased the capacity of the building to approximately 90 beds. A heating plant, tunnels between the buildings, lighting of the roads, grading of the grounds, the addition of a recreation building and other improvements have greatly aided in making Glencliff meet the requirements of a modern sanatorium.

The infirmary building contains an excellent operating room, and facilities for pneumothorax and some other forms of chest surgery, such as pneumolysis and phrenicectomy. The more serious operations in chest surgery such as thoracoplasty, are performed at the New England Deaconess Hospital in Boston by Dr. Richard H. Overholt, or at the Mary Hitchcock Memorial Hospital at Hanover, New Hampshire, by Dr. Dawson Tyson.

The sanatorium at Glencliff has approximately 140 beds at the present time. The policy of the institution is to restrict admissions to a class of cases designated as "favorable," such as first-stage and second-stage patients not carrying persistent temperatures, and cases without complications.

Application for admission to the New Hampshire State Sanatorium is made to Dr. Robert M. Deming. Any physician may write or telephone for an application blank. On receipt of the application Dr. Deming may request an x-ray film of the patient's chest. After study of the facts rela-

tive to the stage of the disease and the prognosis, the superintendent may accept the case. If rejected because of an unfavorable outlook, the case is referred to the State Board of Public Welfare for admission to the Pembroke Sanatorium.

In 1911, recognizing the principle that advanced cases should be treated in institutions readily accessible to relatives and friends, the State of New Hampshire inaugurated the policy of providing a subsidizing appropriation for the treatment of advanced cases of tuberculosis and for the encouragement of the establishment of institutions for their care. Under this appropriation only the cost of maintenance of beds is provided, and the advanced-case work has been carried on at the Pembroke Sanatorium.

This institution, one of the oldest sanatoriums in the country, established in 1900, is located at an elevation of 650 feet—high on the crest of the Pembroke hills—in the town of Pembroke. Being thirteen miles north of Manchester and five miles south of Concord, it is near the center of population of nearly 75 per cent of the State.

Consisting in the early days of an administration building and three camps for approximately 20 patients, the institution has now grown to a 100-bed capacity. With the beginning of the state work, the camp idea has been gradually abandoned and frequent additions have been made to the administration building. The facilities now available provide hospital rooms for each patient. All the buildings are protected against fire by a sprinkler system and other devices. All modern facilities for diagnosis and treatment are now available, with an x-ray department and an operating room for pneumothorax, pneumolysis and similar operations. As is the procedure at Glencliff, thoracoplasty cases are sent to the New England Deaconess Hospital or the Mary Hitchcock Memorial Hospital.

The State's work for tuberculous children has been developed at the Pembroke Sanatorium. Excellent facilities are available for boys and girls. A school is maintained on the sanatorium grounds, and the curriculum and program are carried out in accordance with the requirements of the State Board of Education.

All the patients at the two sanatoriums are state beneficiaries, some paying part of the cost of treatment. The State Department of Public Welfare passes on the admissibility of patients as state beneficiaries, the State assuming entire or partial expense as the financial status of the patient and his family warrants. For the most part, patients are given full state aid.

Many physicians refer their patients to the clinics now so advantageously located through-

out the State and maintained under the auspices of the New Hampshire Tuberculosis Association. These clinics assume the responsibility of making an application for admission of patients to Glencliff or Pembroke, as the findings warrant.

The efficacy of the treatment of tuberculosis in the State of New Hampshire can be readily seen by comparing the death rate of 150 per 100,000 in 1910 with that of 38 in 1935. This was the lowest of any of the New England states and about 20 units lower than the country as a whole. This good showing can be bettered by an increased effort to detect the disease in childhood, which can be accomplished by skin tests, x-ray photography and careful physical examinations.

STATE BOARD OF HEALTH

Probably the most far-reaching of any of our public-health organizations is our State Board of Health. This is composed of six members. The governor and attorney general are ex-officio members, and in addition the law provides that there shall be three physicians and one civil engineer, two of the latter four appointed biennially by the governor, with the advice and consent of his council, to serve for terms of four years. The last legislature added one more lay member. The administrative head is a physician trained in public-health work, who acts as secretary, and is also, by law, the registrar of vital statistics and the state pathologist. Under him function the following departments:

Department of Vital Statistics. This office does the tabulating, recording and preserving of all vital-statistics material. This work has been greatly increased since the passing of the Social Security Act. In 1934, there were only 1432 inquiries, as compared with 3025 in 1938.

Department of Venereal Disease Control. This department operates six clinics, situated in Manchester, Dover, Nashua, Portsmouth, Concord and Berlin. These clinics care for patients who are financially unable to be treated by private physicians. The division supplies private physicians with medication for the treatment of syphilis. During 1938 there were distributed 9201 doses of arsenicals and 9441 doses of bismuth.

Division of Maternal and Child Health. The director of the division is a physician. Its activities are as follows: the organization and maintenance of child-health conferences, where approximately 500 babies are seen each year, the maintenance of three prenatal clinics, serving about 1200 mothers, the distribution of educational literature, the employment of a full-time nutritionist, who gives advice to other state depart-

ments, local relief agencies, nursing organizations and lay groups. The director carries on an annual study of maternal deaths and stillbirths trying to determine their cause and the means of reducing them. This is done in conjunction with the New Hampshire Medical Society and the director acts as the go-between for the Society and the doctors. Through this co-operation it is hoped that there will be a better practice of obstetrics. The division also licenses all maternity hospitals and homes, of which there are about 150 in the state.

Division of Crippled Children's Services This division provides for the registration hospital care, furnishing of appliances and aftercare services—including nursing and physiotherapy—to crippled children under the age of twenty-one. It also supervises clinics in Manchester, Nashua, Concord, Keene, Peterborough, Laconia and Littleton. Approximately 350 crippled children are aided during the year.

Division of Epidemiology This division has charge of the communicable-disease-control work of the Board of Health. An exception is made in the tuberculosis work which is carried on mainly by Dr Robert B. Kerr, under the direction of the New Hampshire Tuberculosis Association. Dr Kerr co-operates closely with the State Board of Health.

Division of Chemistry and Sanitation The chief activity of this department is supervision of the food and drug supply and general sanitary conditions of the entire State. The division consists of a director, a staff of chemists and a bacteriologist who perform the laboratory analyses, and a staff of sanitary engineers and sanitarians who carry on the field work in sanitation. The duties of the laboratory include the chemical and bacteriological examination of drinking water and the analysis of milk, foods, drugs, cosmetics, liquor and such other materials as may affect the public health. The field work consists of supervision and control of public water and sewage systems and of milk supplies including dairies and pasteurization plants. Regular inspections are made of grocery stores, drugstores, restaurants, hotels, overnight camps, tourist places, juvenile camps, lumber camps and many other establishments which serve food and offer lodging to the public. It also has licensing and regulatory control over many of these activities. The industrial hygiene unit of this division is prepared to give technical service and advice to industrial plants in the control and prevention of occupational diseases.

Division of Public Health Nursing This department employs thirteen regular public health nurses doing full time work, three substitutes and nine WPA nurses. It co-operates with all divisions of the Board of Health where nursing services are required.

Division of Bacteriology, Serology and Pathology It is probably with this division that physicians are best acquainted, and I am sure that we all appreciate the co-operation and help which it gives us. The main laboratory is situated in the State House in Concord and a branch is maintained at the Dartmouth Medical School at Hanover. Both are equipped and staffed to perform all standard bacteriological and serological procedures, and the laboratory at Hanover does the pathological work for the department. Since the blood test law has been in operation there has been a tremendous increase in the volume of serological work. The department is always ready to inaugurate new procedures that will be of service to the physician. Appreciating the value of serum treatment in certain types of pneumonia, it has added the service of typing sputums and furnishing serum where indicated. In order to obtain the best results, the members of the department ask that physicians take the sputum as early as possible in the course of the disease, give a history of the case and report on the results of the treatment. The laboratory gives twenty-four hour service in pneumonia typing. This is a distinct advantage, as the efficacy of serum treatment is dependent on early administration.

During the year ended March 31, 1939, a total number of 81,261 tests were carried out. I am sure you will agree that this is a vast amount of work, and it goes to show the confidence that physicians have in the State Laboratory.

MISCELLANEOUS

There are a number of other agencies concerned in public health work in New Hampshire. Notable among these are the State Board of Education, the Department of Public Welfare, the Cancer Commission and many licensing boards and extension services.

* * *

All these activities, with their ramifications, show the necessity of some means of co-ordinating these independent agencies. Logical suggestions and possibilities have been very clearly outlined in the survey, *The Administration of Public Health in New Hampshire*,² published by the New Hampshire Foundation.

The New Hampshire Medical Society represents

tive to the stage of the disease and the prognosis, the superintendent may accept the case. If rejected because of an unfavorable outlook, the case is referred to the State Board of Public Welfare for admission to the Pembroke Sanatorium.

In 1911, recognizing the principle that advanced cases should be treated in institutions readily accessible to relatives and friends, the State of New Hampshire inaugurated the policy of providing a subsidizing appropriation for the treatment of advanced cases of tuberculosis and for the encouragement of the establishment of institutions for their care. Under this appropriation only the cost of maintenance of beds is provided, and the advanced-case work has been carried on at the Pembroke Sanatorium.

This institution, one of the oldest sanatoriums in the country, established in 1900, is located at an elevation of 650 feet—high on the crest of the Pembroke hills—in the town of Pembroke. Being thirteen miles north of Manchester and five miles south of Concord, it is near the center of population of nearly 75 per cent of the State.

Consisting in the early days of an administration building and three camps for approximately 20 patients, the institution has now grown to a 100-bed capacity. With the beginning of the state work, the camp idea has been gradually abandoned and frequent additions have been made to the administration building. The facilities now available provide hospital rooms for each patient. All the buildings are protected against fire by a sprinkler system and other devices. All modern facilities for diagnosis and treatment are now available, with an x-ray department and an operating room for pneumothorax, pneumolysis and similar operations. As is the procedure at Glencliff, thoracoplasty cases are sent to the New England Deaconess Hospital or the Mary Hitchcock Memorial Hospital.

The State's work for tuberculous children has been developed at the Pembroke Sanatorium. Excellent facilities are available for boys and girls. A school is maintained on the sanatorium grounds, and the curriculum and program are carried out in accordance with the requirements of the State Board of Education.

All the patients at the two sanatoriums are state beneficiaries, some paying part of the cost of treatment. The State Department of Public Welfare passes on the admissibility of patients as state beneficiaries, the State assuming entire or partial expense as the financial status of the patient and his family warrants. For the most part, patients are given full state aid.

Many physicians refer their patients to the clinics now so advantageously located through-

out the State and maintained under the auspices of the New Hampshire Tuberculosis Association. These clinics assume the responsibility of making an application for admission of patients to Glencliff or Pembroke, as the findings warrant.

The efficacy of the treatment of tuberculosis in the State of New Hampshire can be readily seen by comparing the death rate of 150 per 100,000 in 1910 with that of 38 in 1935. This was the lowest of any of the New England states and about 20 units lower than the country as a whole. This good showing can be bettered by an increased effort to detect the disease in childhood, which can be accomplished by skin tests, x-ray photography and careful physical examinations.

STATE BOARD OF HEALTH

Probably the most far-reaching of any of our public-health organizations is our State Board of Health. This is composed of six members. The governor and attorney general are *ex-officio* members, and in addition the law provides that there shall be three physicians and one civil engineer, two of the latter four appointed biennially by the governor, with the advice and consent of his council, to serve for terms of four years. The last legislature added one more lay member. The administrative head is a physician trained in public-health work, who acts as secretary, and is also, by law, the registrar of vital statistics and the state pathologist. Under him function the following departments:

Department of Vital Statistics. This office does the tabulating, recording and preserving of all vital-statistics material. This work has been greatly increased since the passing of the Social Security Act. In 1934, there were only 1432 inquiries, as compared with 3025 in 1938.

Department of Venereal Disease Control. This department operates six clinics, situated in Manchester, Dover, Nashua, Portsmouth, Concord and Berlin. These clinics care for patients who are financially unable to be treated by private physicians. The division supplies private physicians with medication for the treatment of syphilis. During 1938 there were distributed 9201 doses of arsenicals and 9441 doses of bismuth.

Division of Maternal and Child Health. The director of the division is a physician. Its activities are as follows: the organization and maintenance of child-health conferences, where approximately 500 babies are seen each year, the maintenance of three prenatal clinics, serving about 1200 mothers, the distribution of educational literature, the employment of a full-time nutritionist, who gives advice to other state depart-

topic gestation, in cases of hydatid mole and in cases of chorionepithelioma, both in men and in women. It is the material which gives the positive tests for pregnancy. Although commonly referred to as anterior pituitary like substance, or A.P.L., its proper appellation is chorionic gonadotropin. It is inactive on oral administration, and can be given safely only by the intramuscular route.

The functions of chorionic gonadotropin in human pregnancy are not clearly known, but its rapid appearance in the blood and urine following implantation of the ovum is assumed to result in the inhibition of menstruation, either directly or through stimulation of the corpus luteum of pregnancy. Because it is a potent stimulator of corpora lutea experimentally, and because its appearance coincides with failure to menstruate and with the development and persistence of the corpus luteum of pregnancy, we naturally believe that it ought to have therapeutic value in stopping functional flowing and in stimulating luteinization. Presumably in sufficient dosage it would accomplish both these aims, but the material has not been chemically identified and the available preparations are neither pure nor really potent. There is at present no proof that these preparations, in the amounts given stimulate or enhance luteinization in women's ovaries or even produce follicle ripening as they do experimentally. There is, however, considerable clinical support for their value in inhibiting truly functional uterine bleeding, although not consistently in the amounts injected. The mechanism of this inhibition is unknown. Until recently no standard of assay for chorionic gonadotropin had been adopted universally, so that what one manufacturer labeled as 100 rat units might have been less or more than 100 rat units according to the standard of another concern. Considering the large amounts of this hormone in the blood and urine of pregnant women, it is only logical that large amounts must be administered to obtain clinical results. This hormone is worth a trial, then, in otherwise recalcitrant true functional flowing.

Estrogenic substances are covered by various terms such as female sex hormone, ovarian hormone. Folliculin, estrin and Menformon. They are derived from urine of pregnant women, human placentas and pregnant mares' urine. The difficulty in naming estrogenic substances is apparent, for there are three of them: the so-called native estrogens, and they have a number of functions. The names of these, estrone, estriol and estradiol, connote only one of their functions, that is, the ability to produce an objective sign of estrus,

namely desquamation of cornified cells from the vaginal mucous membrane. The structure of these hormones and their chemical interrelations have been well established. So far as we now know, they all are similar as regards their physiological properties, although they differ in estrogenic potency. In experimental work the estrogens have been found to have many interesting effects, but their roles in normal and pathologic states in women are only now beginning to be exposed. In adequate dosage they are effective both when taken by mouth and when injected intramuscularly, usually in solution in vegetable oil. By mouth five to ten times as much is necessary as by injection. The estrogens in any of the amounts thus far given to human beings are apparently harmless. This is not surprising considering the enormous quantities elaborated in the body, especially during the latter months of pregnancy.

Let us review some of the actions of the estrogens. Menstruation has been prevented by the administration of tremendous amounts. Presumably, functional flowing could also be stopped in this way. It would be a costly therapy, and on theoretical grounds might be harmful. The giving of estrogen to animals under certain conditions results in enhancement and persistence of their corpora lutea with prolonged progesterin effects. On this basis the administration of estrogen to women at the time of ovulation and luteinization ought to foster a better progesterin effect. This is one reason for prescribing estrogen for sterile women, together with the performance of other maneuvers. Right from the start of pregnancy in women there is marked and progressive increase in estrogen production, apparently first by the ovary and then by the placenta. So we think of estrogen as involved in the stimulation and enhancement of progesterin, which is so important for preparing the ovum's implantation site and for the maintenance of pregnancy.

The estrogens are necessary for proliferation of the endometrium, and progesterin, in turn, cannot act satisfactorily unless the endometrium has been prepared by estrogens—nor can progesterin continue to be effective without estrogens.

As regards lactation, the breasts will not respond fully to the lactogenic hormone of the pituitary gland unless estrogens and progesterin have played a part in their preparation. On the other hand, lactation will not take place if there is too much circulating estrogen, as in cases with retained functioning placental tissue, which probably secretes the tremendous amounts of estrogen found in pregnancy. Therefore, in order to prevent lactation the administration of much estrogen may be

undertaken in conjunction with but not to the exclusion of the usual simple measures

Sore breasts before menstruation are thought to be associated with some imbalance of the pituitary and ovarian hormones that affect the breasts. The condition has not yet been explained, though empirically estrogens often provide relief. Some patients with unmistakable cystic disease of the breasts, especially if there is associated pain, seem to be benefited by prolonged ingestion of estrogen, but there is as yet no clear indication for such therapy, and relief thereby cannot be confidently anticipated in any given case. Our knowledge of the etiology of cystic disease is still too hazy.

Estrogens are necessary for the growth and activities of the uterus, tubes and cervix. They play a large part in the pelvic blood supply, as evidenced by the vascular hypertrophy of pregnancy on the one hand and the atrophy of castration on the other—and these vascular effects include the vagina and vulva. In addition, the estrogens have a direct influence on the epithelium and underlying tissues of the vagina and vulva, causing the epithelium to thicken and the underlying tissues to become more elastic. Hence the rationale of estrogen therapy in vaginitis, both prepubertal and senile, in conditions associated with vulval atrophy, such as kraurosis and leukoplakia, in genital hypoplasia and in conditions, such as amenorrhea and sterility, where an increase of these effects seems desirable.

Progesterin, a secretion of the corpus luteum and of the placenta, is chemically not very different from the estrogens and is rather closely related to the male hormones. Interestingly enough, some of its actions can be duplicated with male hormones. Progesterin for clinical use is synthesized under the name of progesterone. Progesterin, of course, is necessary for the proper preparation of the endometrium for nidation of the fertilized egg and for the development of the decidua, in fact, it appears to be necessary throughout the whole of pregnancy. This substance can inhibit menstruation, and stops functional flowing if given in large enough amounts, but it is still costly to make and much more costly to buy. There seems to be no clear indication for it in the treatment of essential dysmenorrhea, especially since this type of dysmenorrhea characteristically occurs in patients who ovulate and have corpus luteum activity. Since progesterin is so important in pregnancy, one thinks of it in connection with habitual abortion and threatened miscarriage or premature labor, and it certainly rates a trial in these conditions, but not in homeopathic doses. If, in adequate dosage, it fails to prevent abortion, we must remember that a large percentage of spontaneous

abortions are sequelae of blighted ova. Miscarriage or premature labor, of course, may be due to other known and unknown causes in addition to possible lack of progesterin. This hormone must be injected intramuscularly. With the quantities thus far tried, no sign of toxicity has ensued.

Before proceeding with considerations of possible practical uses of the hormones in specific clinical situations, I should like to pass judgment on the hormone tests. In the first place, as I see it, the chief value of the pregnancy tests (for the presence of chorionic gonadotropin) lies in helping to make the diagnosis of chorionepithelioma, and in detecting its early recurrence. As regards normal pregnancy, these tests simply confirm one's suspicions a little earlier than otherwise, and thereby allay the suspense of waiting until the diagnosis is obvious. In the differential diagnosis and treatment of ectopic gestation one must be guided by clinical judgment. In cases with disease contraindicating gestation the diagnosis becomes apparent in ample time for proper measures. Unorthodox and provocative as the statement may seem offhand, I know of no instance in which a pregnancy test was absolutely necessary for the proper clinical management of a case—with the exception of mole or chorionepithelioma. Furthermore, tests for the pituitary gonadotropic factor in human urine, by the methods available and in the present state of our knowledge, are in our experience of no clinical value. Finally, tests for estrogenic substances are still in the realm of research. Since the normal levels of urinary estrogens vary over wide limits throughout normal cycles, repeated specimens over a period of at least one month must be analyzed in order to secure any information about an individual case. Methods of analysis have not been standardized. They are expensive and time-consuming. There is no specific chemical reagent that can measure the estrogens with any degree of accuracy, and bioassay, in order to give dependable results, requires a large number of animals. For these reasons, tests for estrogens are of no practical value to the clinician attempting to diagnose a case. The best test for the presence of the corpus luteum hormone in the non-pregnant woman is to obtain by suction curet a biopsy of the endometrium before menstruation. If it shows a secretory, that is, a progestational, endometrium, this is definite evidence of the presence of progesterin. Progesterin is not excreted in the urine as such, it is found there in the form of pregnandiol, and in such small amounts in the non-pregnant that the test for it is really only qualitative and hence gives no more information than does a biopsy.

Thus, although investigation of the blood content and urinary excretion of these hormones and their metabolic products is slowly increasing our knowledge and understanding it is a waste of money to have any but the pregnancy test done as a clinical procedure. I myself believe this is performed too often to confirm already suspected normal pregnancies, and too infrequently on patients who are candidates for chorionepithelioma to facilitate the diagnosis for which repeated quantitative assays on blood serum are even more preferable.

CLINICAL CONSIDERATIONS

There is no hormone therapy for the "bearded lady." It is usually impossible to find the cause of abnormal hair growth much less to stop or cure it. When it is part of an adrenal or ovarian tumor syndrome, that is another story.

There is no female sex hormone therapy for obesity but at this word our thoughts turn to metabolism, thyroid therapy and diets, and this triad it seems to me, is still the backbone and mainstay of the treatment of functional disorders in the female. Obese patients, and those with amenorrhea, dysmenorrhea, profuse menstruation or prolonged flowing of functional origin and sterile women, in the absence of any obvious pathologic condition, deserve a metabolic study, the giving of thyroid preparations on the slightest indication, and a careful revision of the diet.

Sexual frigidity may have such a complex background that a definite place for hormones in its treatment is difficult to determine. A few patients of mine, while taking 200 to 600 rat units of estrogen daily by mouth, have spontaneously volunteered the information that sex activity was more satisfactory.

Amenorrhea, in the absence of demonstrable constitutional disease and of any desire for pregnancy is not in itself an indication for any attempts at treatment beyond the possible giving of thyroid and a complete diet. It is sometimes possible to produce a sort of menstruation by the proper and costly, amounts of estrogen and progestin, but this is valueless without ovulation. When primary amenorrhea is complicated by sterility the problem is at present practically insurmountable. When secondary or acquired amenorrhea is complicated by sterility an occasional success is achieved, but not by sex hormone therapy although this may be considered a supplementary aid. In simple amenorrhea either primary or acquired, we do not usually know where to lay the blame—on the pituitary gland, ovaries, endometrium, blood vessels, nervous system or general imbalance. I know of no labora-

tory procedures that provide a reliable means of differentiating the causes of amenorrhea. Reports are appearing rather frequently on the value of small doses of x radiation to the ovaries in amenorrhea, the rationale being to inactivate completely for a short while such ovarian function as there may be, in the hope that the return of function will be exaggerated to the point of normalcy. The role of inadequate diet in the production of acquired amenorrhea is perhaps too often overlooked. Menstruation may recur within a year on a carefully planned, complete diet. In addition to diet, thyroid and possibly x radiation it seems worth while to prescribe at least 500 rat units of estrogen by mouth daily with the idea of stimulating the whole genital apparatus.

As to sterility, once tubal patency is established by insufflation the condition of the cervix and vagina rendered satisfactory the occurrence of ovulation indicated by a secretory endometrium on biopsy late in the menstrual cycle and the semen found adequate, sterile or infertile couples seem to be helped more by the mechanical procedures of insufflation or endocervical irritation following intercourse between eight and fifteen days after the start of menstruation than by any hormone administration. Beyond the giving of dietary instructions and thyroid I make it a routine to prescribe 200 to 400 rat units of any sort of estrogen by mouth daily for the woman for months. The rationale for such estrogen therapy lies in the possibility of enhancing the influence of the ovarian hormones on the whole genital tract. This measure has seemed in quite a few patients, to have played a role in achieving the desired result.

For the treatment of essential dysmenorrhea the administration of any of the sex hormones has no proved physiological rationale and cannot be counted upon for any effect. This disability can be so favorably influenced by so many empirical procedures—general health measures, antispasmodics, sedatives, heat, dilatation of the cervix and so forth—that in the ordinary case it seems unwise to resort to hormonal therapy until more information is available. However, I do not wish to go on record as decrying completely the use of hormones for essential dysmenorrhea. After all patients have experienced relief from the premenstrual or early menstrual administration of chorionic gonadotropin, or of large amounts of estrogen or of moderate doses of progestin or from the injection of large amounts of estrogen earlier in the cycle or from the daily ingestion of estrogen throughout the cycle. Such results cannot be entirely a matter of coincidence since these hormones are so causally involved in endometrial

UREMIA FOLLOWING X-RAY THERAPY IN LEUKEMIA*

DUDLEY MERRILL, M.D.†

CAMBRIDGE, MASSACHUSETTS

THE rarity with which uremia is mentioned in the literature as complicating the x-ray treatment of leukemia prompts the reporting of 3 such cases, seen during the last five years

From 1927 to 1939, 40 cases of leukemia, myeloid, lymphatic or monocytic, were treated at the Pondville Hospital. In 18 of these death occurred at the hospital or within twenty-four hours after leaving it. Three of the latter cases, which were associated with uremia and occurred shortly after the administration of x-ray therapy, form the basis of this report.

As early as 1870 Salkowski¹ demonstrated an increased output of uric acid in the urine of a patient with "splenic leukemia." This finding has been confirmed by many later authors. Magnus-Levy, Pribram and Rotky, Brugsch and Schittenhelm (quoted by Jugenburg and Tschotschia²). Studies following x-ray therapy have shown a still further increase in uric acid excretion, as noted by Musser and Edsall,³ Lossen and Morawitz and others (quoted by Jugenburg and Tschotschia²), Joel⁴ and Bedrna and Polcak.⁵ The occurrence of gout as a result of hyperuricemia in leukemia was reported as a rare complication by Brugsch and Schittenhelm in 1908 (quoted by Jugenburg and Tschotschia²).

Bedrna and Polcak⁵ have reported 2 cases of leukemia (1 myeloid and 1 lymphatic) which within a few days of x-ray therapy developed ureteral obstruction from uric acid calculi. The calculi were passed following ureteral catheterization and the patients left the hospital a few days later, benefited by their x-ray treatment.

Jugenburg and Tschotschia² in a most interesting paper, published in 1931, reported some detailed studies of the uric acid metabolism in cases of leukemia undergoing x-ray treatment. A translation of their conclusions is as follows:

The state of the purine metabolism is a measure of the clinical severity of the leukemia.

Increasing blood uric acid can be caused either by increasing destruction of nuclei of white cells or diminished excretion because of renal insufficiency.

In cases responding favorably to x-ray there is an increased urinary output and a normal blood level of uric acid at the end of treatment.

In fatal cases of leukemia severe changes in the kidneys can be demonstrated. These changes are partly of a de-

generative nature and partly leukemic infiltrations of either myeloid or lymphatic cells.

In fatal cases of leukemia there is always diminished excretion of uric acid and accumulation of the same in the blood. [This would hardly seem to apply to cases dying of sepsis without elevation of the nonprotein nitrogen.]

The determination of the uric acid quotient [a figure obtained by dividing the blood uric acid in milligrams per 100 cc. by the twenty-four-hour urinary uric acid output in grams] is just as important as the examination of the peripheral blood during x-ray treatment.

A significant increase of the uric acid quotient shows the approach of menacing intoxication.

In the treatment of leukemia one must take great care to relieve the organism as much as possible from endogenous and exogenous uric acid. Therefore the diet should be as low as possible in purines and x-ray should be given in small doses.

Every case of leukemia should be regarded as having more or less renal insufficiency.

In their paper Jugenburg and Tschotschia cite 4 cases with falling uric acid quotients associated with good responses to x-ray therapy, and 4 cases with rising quotients and death occurring shortly after completion of the x-ray treatment. In 2 of their reported fatal cases the patients died with blood uric acid levels of 132 and 160 mg. per 100 cc., whereas the other 2 had levels of only 61 and 53 mg.

Nemenow,⁶ working in the same Leningrad clinic as Jugenburg and Tschotschia, applied their findings to the planning of x-ray therapy. From their demonstration of the importance of the functional efficiency of the kidneys in determining the response to x-ray treatment, he reasoned that it should be given in small doses at generous intervals in order to spare the kidneys as much as possible, and that it should first be applied directly to the kidneys, in order to remove leukemic infiltrations therein and thus increase their functional efficiency before loading them with uric acid from x-ray treatment applied over other bulky leukemic deposits, such as those in the spleen, lymph nodes and bone marrow.

Nemenow suggested treating the right kidney before the left because of the possibility of some effect on the spleen while radiating the left kidney. He used initial doses of 125 to 240 r. He reported 2 cases of myeloid leukemia treated in this way. The first had a blood uric acid content of 10 mg. per 100 cc. and a uric acid quotient of 188 at the beginning of treatment. The blood uric acid content was reduced to 4.8 mg. and

From the Pondville Hospital, Massachusetts Department of Public Health, Wrentham, Massachusetts.

†Assistant visiting physician, Pondville Hospital, Wrentham, Massachusetts.

the quotient to 4.4 after radiating the kidneys alone. The second case had a blood uric acid content of only 6.6 mg per 100 cc., but a quotient of 13, which was reduced to 3, with a corresponding reduction of the blood uric acid content to 4 mg. Both cases were markedly benefited by x-ray therapy.

The following case illustrates a fatal uremia following x-ray therapy for leukemia.

CASE 1 (P. H. No. 12941) A M., a 56-year-old man was referred to the hospital for x-ray treatment of myeloid leukemia on August 21, 1937. He gave a history of increasing weakness, pallor and a loss of 30 pounds of weight in 3 years; increasing dyspnea and verugo for 3 months and deafness for 2 weeks.

On physical examination the only significant findings were bilateral deafness and an enlarged spleen, extending from the left flank to the midline and from the costal margin to the umbilicus. The hemoglobin was 54 per cent (Sahli); the red-cell count 2,940,000 and the white-cell count 237,500. The differential count showed 71 per cent polymorphonuclears, 1 per cent lymphocytes, 2 per cent eosinophils, 5 per cent basophils, 12 per cent myelocytes, 6 per cent metamyelocytes and 3 per cent myeloblasts. The platelets were present in normal numbers in the smear and the red cells showed marked anisocytosis. The nonprotein nitrogen was 52 mg per 100 cc. The phenolsulfonphthalein excretion of the kidneys was 15 per cent in the 1st hour and 15 per cent in the 2nd, a total of 30 per cent in 2 hours.

The patient received 900 r of x-ray in divided doses applied to the spleen. The white-cell count had dropped to 15,000 at the time of his discharge a month later. The spleen became barely palpable, the verugo disappeared but the deafness was unaltered.

The patient returned to the hospital 9 months after his first admission because of discomfort in the region of the spleen. The latter extended 6 cm below the costal margin. The white-cell count was 341,200 and the hemoglobin 52 per cent. Another 900 r was delivered to the spleen in nine treatments and 900 r was also given on each side of the head in the hope that the deafness might be improved if caused by leukemic infiltration of the 8th nerves.

After 1 month in the hospital the patient was discharged with a white-cell count of 34,000 and a considerably smaller spleen but without any improvement of hearing. He returned again 5 months later (15 months after his first admission) because of pain in the left side and weakness. The spleen was again 6 cm below the costal margin and there was a coarse friction rub audible and palpable over it. The white-cell count was 269,000. The patient received 800 r applied to three different areas of the spleen. He was again discharged considerably improved after a month's stay with a white-cell count of 97,000, a hemoglobin of 47 per cent and a red-cell count of 2,340,000.

The patient re-entered the hospital for the fourth and last time 3 months later (19 months after his first admission) because of recurrence of pain in the left flank. The spleen extended below and to the right of his umbilicus and there was a friction rub over it, again both audible and palpable. The white-cell count was 210,000, the hemoglobin 60 per cent and the red-cell count 2,950,000. The blood nonprotein nitrogen was 47 mg per 100 cc.

X-ray treatment was repeated this time four treatments of 100 r each being applied to two portals 10 by 15 cm. over the front and back of the spleen on successive days.

The white-cell count dropped rapidly to 90,000 in the first 11 days after admission. Two weeks after entry the patient complained of burning on urination and vague abdominal pain and distention. Two days later he began to vomit and seemed a little drowsy. The white-cell count had dropped to 39,500, the hemoglobin to 57 per cent and the red-cell count to 2,910,000, but the nonprotein nitrogen had risen to 148 mg per 100 cc. and the phenol sulfonphthalein test showed no excretion of the dye in 2 hours. Six days later (3 weeks after admission) the white-cell count was 9400, the nonprotein nitrogen 151 mg per 100 cc., the creatinin 9.76 mg and the uric acid 12.3 mg. From this time on the patient's condition steadily became worse; the white-cell count continued to fall until 2 days before death (32 days after admission) when it was 3800 and the nonprotein nitrogen was 244 mg per 100 cc.

Autopsy. A postmortem examination showed the usual findings of chronic myeloid leukemia, but the kidneys were of unusual interest. The right kidney weighed 235 gm. The cut surface showed a cortex of normal width. The capsule stripped with ease, leaving a coarsely granular surface. In the calyces were moderate numbers of small, yellowish gray calculi. There was no obstruction of the ureter. The left kidney weighed 250 gm. In its upper pole was a cyst 7 cm. in diameter filled with clear fluid and having a smooth lining. On section the cortex measured up to 8 mm. in thickness. Scattered throughout the cortex and medulla were many small gray foci on a yellowish-pink background. The capsule stripped easily leaving a coarsely granular surface. The calyces were packed with gravel-like calculi having a yellowish gray color. In the two major calyces were larger stones measuring 2 by 1 by 1 cm. Their surfaces were smooth. Chemical tests showed these calculi to be composed of uric acid and urates. The first portion of the left ureter was packed with gravel-like calculi; the remainder of it was normal.

Microscopic examination showed an occasional small cortical scar in the left kidney containing atrophic tubules and rare hyalinized glomeruli. Scattered collecting tubules in the cortex and medulla contained a finely and coarsely granular basophilic material. The epithelium of some of these tubules was degenerated. In the right kidney were multiple foci of necrosis in the cortex and medulla having the appearance of that of an ascending infection. The foci were heavily infiltrated by polymorphonuclears and often contained fibrin and large clumps of bacteria. Near-by tubules and stroma contained polymorphonuclears. There was slight intimal thickening and hyalinization.

It is possible that this patient's uremia was precipitated by x-ray therapy. However it is interesting that on three previous occasions he had tolerated larger amounts of x-ray delivered to the spleen with gratifying clinical improvement even though he gave laboratory evidence on his first admission of definitely impaired kidney function.

The following cases are not so striking as the first but are reported as representing possible examples of renal insufficiency accentuated by x-ray treatment of leukemia.

CASE 2 (P. H. No. 7539) J. D., a 51-year-old woman, was sent to the hospital on March 3, 1934 with a diagnosis of malignant melanoma of the leg. Six years previously she had first noticed a small "pimple" on her left leg.

This had grown slowly and bled frequently after slight trauma. A doctor had advised its removal a year before admission, but she had refused. Following tonsillitis 3 weeks before entry she noticed some small lymph nodes in the neck. One week later she was seen in a tumor clinic and referred to the hospital with a diagnosis of melanoma. The past history included a radium-induced menopause for menorrhagia 4 years prior to entry.

On physical examination the patient appeared fairly healthy, but there were many small, discrete, relatively soft, freely movable lymph nodes in both sides of the neck, in both axillae and in both groins. These varied from 0.2 to 2 cm in diameter. The spleen filled the entire left flank and descended below the umbilicus. The liver was not felt. There was a mass deep in the right flank which felt like a large kidney. A small, pedunculated, dark-red, vascular tumor about 2 cm in its longest diameter was attached to the skin of the left shin.

The hemoglobin was 66 per cent (Sahlb). The red-cell count was 3,390,000, and the white-cell count 191,000, with 95 per cent mature lymphocytes. A blood Hinton test was negative, and the nonprotein nitrogen was 437 mg per 100 cc. The urine was acid, had a specific gravity of 1.024 and showed a trace of albumin. The sediment showed 15 white cells per high power field.

Diagnoses of chronic lymphatic leukemia and an unclassified papillary tumor of the left lower leg were made.

The patient was given 600 r of x-ray in six treatments, applied to the spleen, three anteriorly and three posteriorly, in 3 days. One hour after the first treatment nausea and vomiting began and lasted for 2 days. Three days later there occurred a transient episode of severe pain in the right flank, associated with localized spasm and tenderness lasting for 2 hours. The white-cell count was 65,000. Three days later the patient had a severe nosebleed, and the following day the white-cell count was 34,500. She felt better, though still a little nauseated and somewhat bothered with burning on urination.

Nine days after the first x-ray treatment there was an attack of severe pain in the left flank, which was thought to be due to a perisplenitis. The urine, however, showed large amounts of albumin and both red and white cells in the sediment. Four days later the white-cell count was 17,900 and the spleen was much smaller although still reaching almost to the umbilicus, but the patient was nauseated and quite drowsy. The next day the nonprotein nitrogen was 204 mg per 100 cc. and the patient was obviously in uremic coma. She died the following day, 15 days after the institution of x-ray therapy.

Autopsy was refused, but a postmortem biopsy of the tumor on the leg was done. This showed the skin heavily infiltrated with newly formed blood vessels, masses of lymphocytes, a few lymphoblasts and some connective tissue. There were many foci of hemorrhage and heavy deposits of golden-brown pigment. A diagnosis of lymphatic leukemia was made.

It seems possible in retrospect that the episodes of severe pain in the flank, first on the right and then on the left, associated with large numbers of white and red cells in the urinary sediment, may have been due to ureteral calculi. It is also possible that x-ray treatment hastened this patient's death, although there was definite evidence of renal impairment before x-ray treatment had begun.

CASE 3 (P H No 11306) E. M. S. P., a 65-year-old woman, was sent to the hospital because of a large spleen on August 13, 1936. She gave a vague history of weakness, a loss of 75 pounds and a lump in her left side for several years and easy bruising and profuse nosebleeds for 1 month. She also had had a lump in her left breast for 8 years, which had been ulcerated for 4 months.

On physical examination the patient was obviously emaciated and chronically ill. In the left breast was a small, hard, nodular, ulcerated mass 3 cm. in diameter, and there was a hard lymph node 2 cm. in diameter in the left axilla. The abdomen was relaxed and the entire left side was filled by a huge spleen extending into the pelvis. The liver edge was felt 4 cm. below the right costal margin. The hemoglobin was 30 per cent (Sahlb), the red-cell count 2,000,000, and the white-cell count 380,000. The differential count showed 60 per cent polymorphonuclears, 5 per cent eosinophils, 2 per cent basophils, 26 per cent myelocytes and 7 per cent myeloblasts. The basal metabolic rate was +39 per cent. A blood Hinton test was negative, and the blood nonprotein nitrogen was 65 mg per 100 cc. The urine showed an acid reaction, a specific gravity of 1.016 and a trace of albumin, the sediment contained 30 white cells and 4 red cells per high power field.

A diagnosis of chronic myeloid leukemia was made, and the question of carcinoma of the left breast was raised. X-ray treatment to the spleen was begun on the day after entry and 100 r was given daily for 4 days. One week after admission the white-cell count was 106,000, but the nonprotein nitrogen had risen to 71 mg per 100 cc. The blood urea nitrogen was 12 mg per 100 cc., the uric acid 273 mg, and the aminoacids 118 mg. Five days later the patient was nauseated and vomiting. Two days later (2 weeks after admission) she was in definite uremia with a nonprotein nitrogen of 147 mg per 100 cc. The white-cell count had dropped to 84,000. The urine showed an acid reaction, a specific gravity of 1.013 and a trace of albumin. The sediment showed 15 white cells and 20 red cells per high power field. Four days later the nonprotein nitrogen had risen to 188 mg per 100 cc. and the white-cell count had fallen to 49,000. Two days later the white-cell count was only 25,100 and the tip of the spleen was just above the umbilicus. The patient was moribund, however, and died the following day, exactly 20 days after the beginning of x-ray therapy.

Autopsy. Postmortem examination, in addition to the characteristic findings of chronic myeloid leukemia, showed a carcinoma simplex of the left breast, with metastases to the axillary nodes. The kidneys showed some grayish white, inspissated material in the right kidney pelvis, and microscopically there were foci of lymphocytic infiltration, hyalinized glomeruli and atrophied tubules. The large vessels showed subintimal thickening. About the pelvic fat in one section was a mass of loose connective tissue in which were collections of leukemic cells.

In retrospect this patient's death quite possibly was accelerated by x-ray therapy, although here too there was laboratory evidence of considerable renal impairment before x-ray treatment was begun.

DISCUSSION

It has been shown that x-ray treatment of leukemia, myeloid or lymphatic, results in an enor-

mous increase of uric acid production within the body which has to be excreted by the kidneys. This increased burden might conceivably precipitate clinical uremia if the kidneys were sufficiently damaged either by leukemic infiltrations or by non leukemic lesions. There is a real danger of the formation of uric acid stones anywhere along the genitourinary tract, which may further hamper the functional efficiency of the kidneys.

With the above facts in mind, the following therapeutic regime is suggested as a means of minimizing the danger of precipitating uremia or the formation of uric acid stones in leukemic patients undergoing x-ray therapy.

(1) Preliminary study of the blood levels of nonprotein nitrogen and uric acid and of the twenty four hour urinary excretion of uric acid before beginning x-ray treatment, and pyelographic and phenolsulfonephthalein excretion studies, if significant nitrogen retention exists.

(2) A low-purine diet and liberal quantities of fluid during x-ray treatment.

(3) Administration of alkalis by mouth in an attempt to keep the urinary reaction alkaline and hence lessen the danger of uric acid stone formation (Barney and Sulkowitch⁷ and Albright⁸).

(4) Administration of cinchophen prior to x-ray therapy in cases having an elevation of the blood uric acid, because of the known effect of cinchophen in increasing the excretion of uric acid by the kidney in cases of gout and leukemia.⁴

(5) Preliminary radiation of the kidneys according to the suggestion of Nemenow.⁶

(6) Blood uric acid and twenty four-hour urinary uric acid output determinations every three or four days during x-ray treatment, as a guide to increasing or decreasing the frequency of treatment.

(7) Treatment of extrarenal leukemic infiltrations by frequent x-ray exposures of small doses, spaced according to information obtained from the study of the uric acid metabolism and the blood counts.

CONCLUSIONS

Uremia is not a rare complication of the x-ray therapy of leukemia.

The number of leukemic patients dying with clinical uremia following x-ray treatment might be reduced by following a regime, as outlined, designed to spare the kidneys as much as possible from becoming overloaded with large amounts of uric acid and to avoid the attendant danger of either uremia or uric acid stone formation, or both.

THE MASSACHUSETTS MEDICAL SOCIETY AND THE BRISTOL SOUTH DISTRICT MEDICAL SOCIETY*

PHILEMON E. TRUESDALE, M.D.†

FALL RIVER, MASSACHUSETTS

IN OBSERVING the centenary of the Bristol South District Medical Society, no more appropriate introduction could be offered by the speaker than the words used by Dr. Edward Reynolds in 1841:

We can hardly assemble on these short occasions without some mutual advantage. If they do not make us much wiser, they always make us happier, for we never separate without some kinder feelings and without acquiring some new interest in each other as well as in the noble cause to which we have consecrated our talents and our lives.

Since we have been on the brink of cataclysmic war for a year or more, we may find profit in reviewing some of the salient points in the stirring times which were successfully bridged by our ancestors. They survived, and so may we. Even Diogenes suffered from the vicissitudes of his time, about 400 B.C. In anticipation of his own death, he directed, "Bury me on my face." When asked why, he said, "Everything will soon be upside down, anyway."

So it is eminently fitting at this time that we should be looking back to the forgotten past, to review some of the great events which led up to the birth of the parent society, and later of this district society, and to gather riches from the memoirs of the great men who labored in laying the foundation of our cultural heritage.

From the settlement of the country in 1620 to the time when the Massachusetts Medical Society was organized in 1781, a period of more than one hundred and sixty years, no systematic effort whatever was made in New England to raise the standard of medical education, or to regulate the practice of medicine. A few able and highly respected physicians, educated chiefly in foreign countries, were to be found in the larger towns, but in general, the profession was in a state of extreme degradation.

A young man who, from choice, ill health or aversion to other pursuits, signified his wish to be initiated into "the arts and mysteries" of healing the sick, would first study Latin grammar with the parish minister as far as the first personal pronoun. Then he would apprentice himself to some

local practitioner for a few months, and, with this meager preparation, enter upon the discharge of his responsible duties. Thus was made the preacher-doctor, the highest type of which was exemplified by Cotton Tufts.

No examination was held, and no license given or required. A skeleton, in those days, was a rare acquisition, and a human dissection created as much consternation among the people as the appearance of a meteor. It was claimed that a knowledge of anatomy was of little importance to a physician, whatever might be the case with respect to the practice of surgery. Medical libraries did not exist, and the few eminent men educated abroad demanded 100 guineas from students, which surpassed the means of those who expected to practice for ninepence the visit. In the cities one shilling and sixpence, and later two shillings, was the customary fee for an ordinary visit.

The American Revolution opened a new field for medical investigation. Joseph Warren, a most conspicuous character of the period, was proposed as physician general, but, preferring a more active, hazardous employment, accepted a major general's commission, and in a few days sealed his principles with his blood at Bunker Hill.

Benjamin Church, a pupil of Joseph Pynchon, was appointed director of hospitals. He served with distinction, but while in office he was charged with treason, tried by court martial in Connecticut and found guilty. He was placed aboard a vessel headed for the West Indies. Nothing was ever heard of him thereafter.

It must be remembered that these were treacherous times. The patriots were virile, courageous men, but suspicious and just plain fighting mad. They brooked no opposition on the part of the native population, and sympathy for the British shown by any of their friends was a criminal offense. Many of the Tory sympathizers, like Edward Augustus Holyoke, were doctors who actually had an impartial attitude, but felt misgivings about the wisdom of undertaking a war against an enemy which was the most powerful nation on land and sea. Holyoke and eleven others suspected of pro-British sentiments were forced to publish a recantation of Toryism on May 30, 1775. Holyoke himself had to make a public declaration on Boston Common.

A discourse delivered at the centennial anniversary of the Bristol South District Medical Society, New Bedford, May 4, 1939.

†Surgeon, Truesdale Hospital, Fall River, Massachusetts.

The prudence and sagacity of Washington, which are as easily traced in the archives of science as in the cabinet or the field, instituted the first medical examinations in this state of candidates for practice.

Harvard Medical School was founded in 1770, on the bequest of Ezekiel Hersey. Three other donors were Abner Hersey, John Cummings and William Erving. The sum bequeathed was four thousand pounds. The medical department was not organized, however, until 1782.

During the Revolutionary War military hospitals afforded extensive opportunities for observations and experiments. Surgeons became familiar with important operations. Anatomy was greatly improved by the frequent unimpeded inspection of the organs of the human body. Physiology was better understood, and a spirit of inquiry assiduously cultivated.

One of the branch hospitals was located in Boston, with peculiar advantages to students in medicine. In 1780, the first course in anatomy was given with dissections and demonstrations by John Warren, surgeon of that establishment. Students of Harvard University were allowed to attend.

In 1780 the American Academy of Arts and Sciences was incorporated. Ten of the original number were of the medical faculty. David Cobb, Edward Augustus Holyoke, Ebenezer Hunt, Charles Jarvis, Joseph Orne, Theodore Parsons, Oliver Prescott, Micajah Sawyer, John Barnard and Cotton Tufts. The charter provided for the advancement of science and the useful arts, and the encouragement of medical discoveries.

In 1783, at Harvard Medical School John Warren was installed as professor of anatomy and surgery, Benjamin Waterhouse as professor of the theory and practice of physic, Aaron Dexter as professor of chemistry and materia medica. In 1809 John Collins Warren and John Gorham were chosen adjunct professors of anatomy and chemistry.

Let us pause a moment to review the activities of that small group of men who flourished during the War of the Rebellion. They were thoroughly familiar with the disorganized state of medical practice which had prevailed. Keenly aware of the necessity for organized effort to promote progress by association and mutual co-operation, they set about the task of establishing a society for this purpose.

The act of incorporation of the Massachusetts Medical Society was sponsored by thirty-one physicians. The preface was as follows:

As health is essentially necessary to the happiness of society, and as its preservation or recovery is closely

connected with the knowledge of the animal economy and of the properties and effects of medicines, and as the benefit of medical institutions formed on liberal principles, and encouraged by the patronage of the law is universally acknowledged

Be it therefore enacted by the Senate and House of Representatives in General Court assembled and by the authority of the same That Nathaniel Walter Appleton William Baylies Benjamin Curtis Samuel Danforth Aaron Dexter Shurley Erving John Frank, Joseph Gardner Samuel Holten Edward Augustus Holyoke Ebenezer Hunt Charles Jarvis Thomas Kist Cites Crouch Kellogg John Lynn James Lloyd Joseph Orne James Pecker Oliver Prescott Charles Pynchon Isaac Rand, Isaac Rand Jr Micajah Sawyer John Sprague Charles Stockbridge John Barnard Sweet Cotton Tufts John Warren Thomas Welsh Joseph Whipple and William Whiting be, and they hereby are formed into, constituted and made a body politic and corporate by the name of THE MASSACHUSETTS MEDICAL SOCIETY and that they and their successors, and such other persons as shall be elected in the manner here after mentioned shall be and continue a body politic and corporate by the same name forever.

And be it enacted by the authority aforesaid That the fellows of said society may from time to time elect a president, vice president and secretary with other officers as they shall judge necessary and convenient and they the fellows of said society shall have full power and authority from time to time to determine and establish the names number and duty of their several officers, and the tenure or estate they shall respectively have in their offices and also to authorize and empower their president or some other officer to administer such oaths to such officers as they the fellows of said society shall appoint and determine for the well ordering and good government of said society provided the same be not repugnant to the laws of this commonwealth.

And be it enacted by the authority aforesaid That the fellows of said society shall have one common seal and power to break, change and renew the same at their pleasure.

And be it enacted by the authority aforesaid That the fellows of said society may sue and be sued in all actions real personal or mixed and prosecute and defend the same unto final judgment and execution by the name of the Massachusetts Medical Society.

And be it enacted by the authority aforesaid That the fellows of said society may from time to time elect such persons to be fellows thereof as they shall judge proper and that they the fellows of said society shall have power to suspend expel or disfranchise any fellows of said society.

And be it enacted by the authority aforesaid That the fellows of said society shall have full power and authority to make and enact such rules and bylaws for the better government of said society as are not repugnant to the laws of this commonwealth and to annex reasonable fines and penalties to the breach of them not exceeding the sum of twenty pounds, to be sued for and recovered by said society and to their own use, in any court of record within this commonwealth proper to try the same and also to establish the time and manner of convening the fellows of said society and also to determine the number of fellows that shall be present to constitute a meeting of said

society, and also, that the number of said society, who are inhabitants of this commonwealth, shall not at any one time be more than seventy, nor less than ten, and that their meetings shall be held in the town of Boston, or such other place within this commonwealth as a majority of the members present in a legal meeting shall judge most fit and convenient.

In the Senate, November 1, 1781

This bill having had two several readings, passed to be enacted

SAMUEL ADAMS,
President

Approved by JOHN HANCOCK

Edward Augustus Holyoke was chosen as the first president of the Society. Four years later, in 1785, advisory committees were appointed for the ten different departments, of which Bristol was the ninth. In 1789, the Society drew up a plan of medical instruction requisite for candidates. The period of instruction was to be three years, with attendance on the practice of a respectable physician. The censors met for examining and licensing candidates for practice once in four months. The first licentiate was admitted in 1782.

The public estimation of this society was manifested in the constant patronage of the government. Its grant of a township of land to the Society demands our most respectful acknowledgment.

During the first ten years the operations of the Society were conducted with vigor. Toward the close of that period, however, unhappy personal alienations among some of the leading members existed, several of the most active of the founders had died or had become too infirm to take part in the meetings as formerly, and the Society languished. From 1794 to 1800 the treasurer was directed not to call on the fellows for the payment of their annual assessments.

In the beginning, the number of members was limited to seventy. After an interval of twenty years, however, it became evident that this limitation of membership was a distinct handicap. By an act of the legislature in 1803 the character of the Society was essentially changed. The number of fellows, originally limited to seventy, embraced all respectable practitioners in physic and surgery, and by 1813 the number had risen to two hundred and four, exclusive of honorary members. At this time the population of Boston was twelve thousand. Membership was not limited to Massachusetts physicians, but included men like Moses Appleton, of Waterville, Maine, Samuel Ayer, of Portland, Maine, William Buel, of Litchfield, Connecticut, Micah Eldridge, of Nashua, New Hampshire, George Hooker, of Syracuse, New York, Usher

Parsons, of Providence, Rhode Island, and Thomas Sewall, of Washington, District of Columbia.

The first volume of medical papers read at the meetings of the Society appeared in 1808. It included the following:

Edward Augustus Holyoke "An Account of the Weather and of the Epidemics at Salem."

Hon. William Baylies "An Account of the Ulcerated Sore Throat as it appeared in the Town of Dighton, 1785 and 1786."

Joseph Orne "Experiments with the Common Cow Parsnip."

Nathaniel W. Appleton "Successful Treatment of a Paralysis of the Lower Limbs, Occasioned by a Curvature of the Spine."

Isaac Rand "A Case of Empyema, Successfully Treated by Operation."

Isaac Rand, Jr. "Observations on Hydrocephalus Internus."

Hon. William Baylies "Calculus in the Ureter."

John Warren "Use and Effect of Mercury."

Josiah Bartlett "Case of Spotted Fever with Dissections."

Thomas Welsh "Dissertation on Heat and Cold."

In this same year appeared the *Pharmacopoeia*, prepared by James Jackson and John Collins Warren.

Thus the standard of medical education was raised and intercourse among the members of the profession improved. The fellows of the Society believed it incumbent upon those who cultivated medicine to keep pace with the general progress of human attainments. Later presidents who maintained the same high standard set by Edward Augustus Holyoke were William Kneeland, Cotton Tufts, Samuel Danforth, Isaac Rand and John Warren.

Ebenezer Alden, in his account of the origin and progress of the Massachusetts Medical Society read May 30, 1838, stated that it could boast of two schools of medicine and that graduates of the Berkshire Medical Institution were entitled to the same privileges as those of the Harvard Medical School. It had a weekly press devoted to medical discussion. Up to the founding of the Society there had been no attempt made publicly in New England to communicate medical instruction, if we except a course of lectures by William Hunter, an eminent physician and surgeon in Newport, Rhode Island, given in 1754-1756, and a short course on anatomical demonstrations in Boston by John Warren, given in the winter of 1780.

Standards of medical practice were raised by the Board of Censors, the members of which were under oath to the faithful performance of their duties, and were subject to a heavy fine for any neglect.

According to Alden, the medical department of

Harvard University was well organized by 1782. At one time, no little friction existed between the faculty of the College and the fellows of the Society on the subject of conferring medical degrees. Finally, by mutual conference the Society obtained assurance that the standard of medical education would not be lowered. Another great benefit to the public good was the legalizing of the study of anatomy. In February 1829 at a meeting of the councilors, a petition was prepared for the legislature asking for a modification of the laws then existing which prohibited the procuring of subjects for anatomical examination.

It was felt, however, that the subject was beset with difficulties, time and effort were needed to prepare the public mind for so great a change. Circulars were distributed to the fellows and to other intelligent and influential individuals. As a result, on February 28, 1831, an act was passed legalizing the study of anatomy, an act which has brought honor on our state as the first to set an example of such enlightened legislation.

An effort was made to suppress quackery, a very difficult task for the Society. All useful discoveries in medicine were made public, especially those relating to epidemics and unusual diseases. Irregular practitioners of every grade were excluded from fellowship in the Society. A system of correct professional conduct was maintained among the members.

I wish now to review briefly the lives of two of the outstanding figures in the founding of the parent society. Edward Augustus Holyoke, the first president of the Society, and William Baylies of Dighton.

Edward Augustus Holyoke was born in Marblehead on August 1, 1728. His father was Edward Holyoke, of Boston, who was educated at Harvard and later became pastor of the Congregational Church in Marblehead. In 1737 he was chosen president of Harvard College. President Holyoke married three times, and Edward Augustus was the offspring of the second marriage. In 1742 the boy entered Harvard College. His thesis subject was *Labor Improbis Omnia Vincit*, a motto which guided his future life. He was graduated in 1746, and began the study of medicine with Dr. Berry, of Ipswich, the most distinguished practitioner of the neighborhood. In 1749 he came to Salem to begin a long and useful practice. Six years later he married Judith Pickman, who died in childbirth. In 1759 he married Mary Viall, daughter of a Boston merchant, and by this second wife he had twelve children, ten of whom died of diseases then prevalent in early childhood.

During Holyoke's lifetime the medical pro-

fession abounded in discouragements which, to say the least, are greatly lessened in our day. The standard of medical education was totally unsettled.

Few physicians have done so much for the profession as did Holyoke. He made an average of over eleven visits a day for seventy-five years. On one occasion when measles was prevalent, in 1787, he made over one hundred professional visits in a day for several days. He was never averse to trying new remedies, but did it with great caution in order to ensure the safety of his patients.

Holyoke had great urbanity of manners, and was what Bacon has styled a full man. His ability and eminence in his profession, united with his great learning and his fine taste for those arts which embellish human life, made him an ornament, not only to his own profession but to the nation and age in which he lived.

In one paper he stated:

It is much to be wished that practitioners would more generally commit to paper their thoughts and remarks upon diseases as they arise, and communicate them to the Society, which though attended with some labor would be amply rewarded by the benefit which would accrue to themselves, their patients and the art they profess.

On August 1, 1828, his one hundredth birthday, Holyoke walked from Salem to Boston in order to attend a public dinner given by his friends. Also the district medical society requested him to sit for his portrait to be placed in its library. By this time he had completed his *Recollections*, a delightful account of his activities. He walked five or six miles daily, rode horseback occasionally, and had excellent health except for impaired hearing. On November 24, 1828, he received an injury to his right leg on stepping out of his carriage, and his health declined steadily thereafter. He died March 21, 1829. A postmortem examination was made and all the local physicians were present. What an example, even for the highly advanced culture of today!

William Baylies was born in Uxbridge on November 24, 1743. He was a man of fine mental endowments, and held many positions requiring high intelligence and sound judgment. He frequently held council with the leaders of the medical profession in New England, and by his associates he was considered a master mind. Graduated from Harvard College in 1760, he went to New Bedford to study medicine with Elisha Tobey. He began to practice medicine in Taunton where he married Bathsheba, the daughter of Samuel White, the first lawyer of Taunton. Their daughter Elizabeth married Samuel Crocker, one of the

first merchants of the town, and one son, Samuel White Baylies, studied law with Governor Sullivan. Another son, William Baylies, of West Bridgewater, was eminent as a lawyer, and still another, Francis Baylies, was one of the leading historians of the Old Colony.

William Baylies was a member of the Provincial Congress, which convened in 1775. During the Revolution, he was often in the councils of the State. In 1784 he was appointed registrar of probate for Bristol County, and was an elector for president and vice-president in 1800. He was an original member of the Medical, the Historical, the Agricultural and the Humane societies of Massachusetts and a fellow of the Academy of Arts and Sciences. A skillful physician and author of many significant medical treatises, he practiced medicine in Dighton for many years.

Altogether too seldom has his name been referred to in the historical references on the early history of the Massachusetts Medical Society, and in this locality there are no commemorative insignia to reveal his importance as one of the founders of the Society.

The two Bristol County medical societies trace their origin to a period when members of the Massachusetts Medical Society were widely scattered throughout the Commonwealth. Travel was slow and expensive. One meeting each year was considered all that the members could reasonably be expected to attend. Therefore, as the Society increased in numbers, district societies were formed, all under the control of the parent society but appointing their own officers, and receiving and disposing of property outside the authority of the Massachusetts Medical Society.

Approaching the time that the Bristol District was formed, it had been the custom of the secretary of the Society to refer to the subdivisions as departments, numbered from one to ten. In 1840, the departments were referred to as districts, designated by the points of the compass. The Southern District included Fall River, New Bedford and the Cape. Later on, the districts were referred to by the county name, and finally, the records show a combination of geographical and county names.

Of the original departments, Bristol was the ninth. The records are in no wise complete, but some facts are known regarding the genesis of the district societies. Because of the difficulties of attending the general meetings, petitions for district societies were presented in the early nineteenth century from members in Suffolk, Essex, Worcester, Berkshire and Hampshire counties, and were granted. These district societies went immediately into active operation, each holding two meetings a year. This arrangement has

proved highly useful, and has continued to the present time. The societies acquired libraries, collected medical periodicals and discussed current local problems. They invited lecturers and encouraged the members to take courses in medicine and anatomy. Physicians in Bristol, Plymouth, Dukes and Nantucket counties petitioned for the establishment of a district medical society at a meeting of the Council held October 3, 1838, and the charter which was subsequently granted resulted in the formation of the Southern Medical District Society. The petition read as follows:

The subscribers hereby make application for the establishment of a district medical society to be called the SOUTHERN MEDICAL DISTRICT SOCIETY, to include the following towns, viz New Bedford, Fall River, Taunton, Freetown, Fairhaven, Dartmouth, and Westport of Bristol County, Middleboro, Rochester and Wareham of Plymouth County, Chilmark, Tisbury & Edgartown of Dukes County and Nantucket, and the place of meeting to be at New Bedford.

PALL SPOONER

SAMUEL SAWYER

JULIUS S MAYHEW

ANDREW MACKIE

WILLIAM C. WHITRIDGE

New Bedford, September 12, 1838

This resolution was submitted by Enoch Hale, S. D. Townsend and John Homans. Soon afterward the name was changed to the Bristol South District Medical Society.

The first officers of the society, as recorded in May, 1840, were

| | |
|-----------------------------------|----------------|
| William C. Whitridge, New Bedford | President |
| Peter Mackie, Wareham | Vice-President |
| Amory Glazier, Fall River | Vice President |
| Samuel Sawyer, Fairhaven | Secretary |
| Paul Spooner, New Bedford | Treasurer |
| William R. Wells, New Bedford | Librarian |

Ten years later, June 20, 1849, the Bristol North District Medical Society was organized to include all fellows of the Massachusetts Medical Society residing in Taunton, Seekonk, Attleboro, Rehoboth, Norton, Mansfield, Easton, Raynham, Berkley, Freetown, Somerset, Dighton and Swansea.

When the state line was changed in 1862, nearly all of Pawtucket and a part of Seekonk were attached to Rhode Island, and members of those places afterward became known as non-resident fellows of the Massachusetts Medical Society.

A glance at the medical history of the State shows that many prominent physicians were practicing before the founding of the Massachusetts Medical Society and before that of the Bristol South District Medical Society.

Before 1800 the medical news and literature from New Bedford emanated mostly from Ebenezer Perry, the only physician of the town. About

the year 1795 his charge for a visit was sixpence and thus he kept all other physicians at a distance. An English lady who was under treatment at this time was so much surprised at the meagerness of his charges that she asked to be furnished with the particulars of the bill, so that she might take it to England. After this, the doctor raised his price to one shilling per visit. It is said that Dr. Perry was a good, plain practical physician and an honest man, but poor. Another prominent physician was Elisha Tobey with whom William Bayles studied before he began his own practice in Taunton. Samuel Perry and his son, Samuel, were early practitioners.

The early members of the Bristol South District Medical Society who practiced in New Bedford were Samuel Perry, 1803, Alexander Read 1816, Paul Spooner, 1821, William C. Whitridge 1822, Andrew Mackie, 1824, Julius S. Mayhew 1830, Lyman Bartlett, 1833, William A. Gordon 1835, Edward W. Greene, 1839, and Elijah Colby 1847.

Alexander Read, a graduate of Dartmouth in 1808, located in New Bedford in 1811.

Paul Spooner opened an office in New Bedford in 1807 and practiced as a successful obstetrician for half a century. He died in 1862 at the age of seventy-six.

William Cushing Whitridge came to New Bedford in 1822 where he practiced until his death in 1857, aged seventy-four years. He served as the first president of the Bristol South District Medical Society.

Julius Stewart Mayhew came to New Bedford as a young school-teacher and gave singing lessons, then entered Harvard Medical School. He came from a long line of physicians, there having been a doctor in each generation of the Mayhew family for hundreds of years. He joined the Massachusetts Medical Society in 1830 and took an active part in organizing the Bristol South District Medical Society. He was a foe to all types of oppression and among the first to cast an Abolitionist vote in New Bedford. In truth, he was a man of the old school.

William Alexander Gordon became a fellow of the Massachusetts Medical Society in 1835. He was born in Newburyport and was graduated from Harvard Medical School. He came to New Bedford in 1839, and took an active part in founding the Bristol South District Medical Society.

Elijah Colby came to New Bedford in 1830 and practiced until his death in 1856. He was treating a patient an hour before his own death. It is said that he was never known to speak a cross word in his life.

The medical history of Fall River began some what later than that of New Bedford. The inhabitants of the town were forced to rely on physicians in surrounding towns for medical aid. The first doctor of the period was Amory Glazier, who began to practice in 1811.

The early members of the Bristol South District Medical Society who practiced in Fall River were Henry Willard 1832, Amory Glazier, 1839, Jason H. Archer 1839, Foster Hooper 1839, Ebenezer T. Learned 1839, William H. A. Crary 1840, Thomas Wilbur, 1841, Phineas W. Leland, 1851 and Jerome Dwelly, 1851.

Henry Willard belonged to the doctor-preacher type.

About 1811 when the population of Fall River was about 1100, Amory Glazier began to practice. He was for some years the only physician in the place. In 1811 he married Ann Chaloner Durfee and lived a long useful life.

Jason Hives Archer began to practice about 1820. Born in Wrentham in 1795, he entered Brown University in 1812 and was graduated in 1816. He then studied medicine with William Ingalls, of Boston. In his home was stored the so-called skeleton in armor which was destroyed in the fire of 1943.

In 1826, when Fall River's population numbered 2000 souls, Foster Hooper began practicing after graduating from the Burlington Medical School. He was in the front rank of his profession and also took an active part in public affairs.

Ebenezer Turell Learned was born in Gardner. He was graduated from Harvard Medical School in 1836, and studied with Perry Bowditch Gould and Wymann, of Boston. He practiced for ten years in Weymouth and then attended Jefferson Medical School. He came to Fall River in 1846. Quiet and reserved, he had a vein of humor and a kindly sympathy which made him the ideal family doctor. He retired from practice in 1883 and died two years later at the age of seventy-two. His son and grandson followed his profession and were blessed with many of his virtues.

By 1840, the population of Fall River was 6735. During this year William Henry Allen Crary began practice there. Born in Assonet in 1817, he attended schools in Fall River and academies in Plainfield and Colchester, Connecticut, going on later to the Berkshire Medical School and then to London, Paris and Dublin. At the time of the first trial of ether in Fall River this anesthetic had been in use for about a year, but physicians were rather slow in adopting it. Hooper and Crary decided to make a personal trial. They went to the office of Ledoyt, a dentist, and

Crary allowed himself to be etherized. Hooper did the administering, but the quantity was not sufficient to produce insensibility to pain, and it had the effect of making Crary decidedly and aggressively nervous. He used his fists, much to the discomfort of Hooper and Ledoyt. Crary married Amy H. White in 1840, and that same year joined the Bristol South District Medical Society. He died at the age of thirty-seven, after a practice of fourteen years.

Thomas Wilbur was born in Hopkinton, Rhode Island. He was graduated from the Yale Medical School in 1824, and studied for a number of years in Philadelphia. He first practiced in Swansea and then came to Fall River. He had seven children. A granddaughter, Dr. Mary W. Marvell, a graduate of Johns Hopkins, is now a physician in Fall River. Wilbur was admitted to the Bristol South District Medical Society in 1841. He died in Missouri, while on a business trip, at the age of sixty-two years.

Phineas Washington Leland was one of the most resourceful and public-spirited physicians of his time. He was born in Grafton in 1798, and studied medicine with George Cheever Shattuck, of Boston, receiving his degree from Bowdoin in 1826. He was collector of customs in Fall River for twenty years. In 1842 he was elected to the State Senate, as president of the Fall River Athenaeum, editor of the Fall River *Patriot* and one of the founders of the Fall River Public Library; he was greatly interested in educational matters. He was admitted to the Bristol South District Medical Society in 1851. He died in 1870, aged seventy-two, after a practice of thirty-six years.

Jerome Dwelly, although born in 1823, was in active practice in the early years of the present century in Tiverton, Rhode Island. He attended Pierce Academy in Middleboro. He studied medicine with Thomas Wilbur and later with William E. Townsend, of Boston. In 1847 he was graduated from the Harvard Medical School and began to practice immediately. With Crary he gave ether successfully, producing complete anesthesia, operating on the son of Thomas Smith, who had been injured by the handle of a paint brush penetrating the muscles of the back. This was the first successful use of ether in this part of the State. Dwelly was city physician in Fall River from 1855 to 1868 and was medical examiner in this district for more than a generation. He died in 1913 at the age of ninety, after a long, active, faithful practice of sixty-four years.

Bearing in mind our heritage from these great physicians of the past, and the final act of its first

president in leaving instructions for his own post-mortem examination, may we not do something constructive in commemorating this anniversary in the nature of an act to improve our standards of practice?

Morbid anatomy may be regarded as one of the essential supports of the medical edifice, the chief cornerstone upon which it may repose in security. All its teachings are facts. We must not withdraw from the age-old recognition of the value of truth in daily practice.

To face the truth at the autopsy table is sometimes humiliating, but far greater progress is made in such self-abnegation than by a wealth of conjecture. Let us launch a movement to encourage physicians of this district and others in the Commonwealth to devise ways and means to educate the public as to the value of the postmortem examination.

Therefore, in closing, I venture to offer this resolution.

WHEREAS, Morbid anatomy is the foundation of medical knowledge, and

WHEREAS, The lessons derived therefrom constitute a most powerful postgraduate study, and

WHEREAS, The number of postmortem examinations now obtained both in hospitals and outside is deplorably small, therefore be it

RESOLVED, That the Massachusetts Medical Society appoint a committee to study the subject with a view of petitioning the General Court of the Commonwealth to increase the facilities for postmortem examination by making available the services of one well-trained pathologist in each district of the Massachusetts Medical Society.*

The preparation of this material in the form of annals or chronicles, including biographical references of the early participants in the affairs of the Bristol South District Medical Society, has been time-consuming but not a chore. It so happens that since 1916 I have been in possession of a complete set of the *Transactions* of the Massachusetts Medical Society from 1781 to 1900. A more interesting, informative and stimulating collection of records would be difficult to find.

I found many personal and interesting references from the pamphlet *Early Physicians of Fall River*, by the late Dr. A. C. Peckham, who was recognized as the historian of the medical profession in this district, where he practiced for more than sixty-five years.

The reader who is interested may find further il-

*The above resolution was unanimously adopted.

luminating material in Dr. Henry R. Viets's book, *A Brief History of Medicine in Massachusetts*.

I regret that time does not permit a report on the contemporary history of the Bristol South District Medical Society. No doubt it is familiar to many of our members, and may be presented on some future occasion. Looking back over the period which I have covered in a somewhat cursory manner, it is apparent that this society has continued to flourish with and in the path of the

parent society. The medical profession of the State of Massachusetts has maintained its prominent position in the advance of medical knowledge. In no other period in the history of medicine have the prevention and cure of disease made such progress as in the past few decades. In this advancement of medical knowledge the fellows of this society as a whole have contributed in full measure.

151 Rock Street.

REPORT ON MEDICAL PROGRESS

BACTERIAL INFECTIONS OF THE GASTROINTESTINAL TRACT*

CHESTER S. KEEFER, MD†

BOSTON

ONE of the major problems in preventive medicine and public health is the control of bacterial diseases of the gastrointestinal tract. It is no exaggeration to say that greater strides have been made in the prevention of these diseases than in any other group of epidemic diseases, with the possible exception of diphtheria. In the Western Hemisphere, at least, the decrease in the number of cases of typhoid fever, infantile diarrhea and dysentery has been brought about through the co-operative activity of physicians, sanitary engineers and public health officials who have devised methods for protecting the food and water supply of the public and for preventing the spread of infection. In spite of all these advances, we must not allow such victories to give us a sense of false security, since the infections mentioned are still far too common in many communities. It is well then, to review some of the features of the various infections which aid in their recognition and prevention.

TYPHOID FEVER

The decline in the number of cases of typhoid fever in the last forty years is one of the remarkable achievements in medicine. In most large hospitals, the disease is indeed rare. The survey of the situation by Dublin and Lotka¹ in their recent book *Twenty-Five Years of Health Progress* serves to stress certain points. First, it is now clear that typhoid fever is more prevalent in small towns or villages than it is in either strictly

rural or urban populations. The explanation for this state of affairs would appear to be the inadequate control of water supply and sewage disposal, as well as a lack of adequate control of carriers and infrequent vaccination.

The recognition of typhoid fever usually causes no difficulties, since the isolation of the typhoid bacillus from the blood, urine or stools or the detection of specific agglutinins in the blood serum of the patient serves to establish the diagnosis. Certain difficulties may arise if typhoid fever develops in a previously inoculated individual or if the disease is very mild. The difficulties in diagnosis in those previously inoculated are most evident in patients who may fail to show bacteremia but who show a positive agglutination test. The question then arises whether the agglutination reaction is evidence in favor of an active infection or only a reaction to the previous inoculation in a patient with another entirely different infection.

When one is confronted with the problem of fever in an individual who has been previously inoculated against typhoid fever and who shows a positive agglutination test but no organisms in the blood, urine or stools, the following procedures should be carried out in order to establish whether or not one is dealing with a case of typhoid fever.

Agglutination tests should be carried out with H and O antigens, possibly with Vi antigen, and they should be done serially, that is, once every five to seven days. Since the interpretation of the results of these tests is of considerable importance in diagnosis, it is necessary to be familiar with their significance.

*From the Thorndike Memorial Laboratory, Second and Fourth Medical Services (Harvard), Boston City Hospital, and the Department of Medicine, Harvard Medical School, Boston.

†Associate professor of medicine, Harvard Medical School; junior visiting physician and director, Second and Fourth Medical Services, Boston City Hospital.

Agglutinins against the H antigen (flagellar antigen) appear in the blood of vaccinated individuals, and may persist for a number of months following inoculation. Their presence, therefore, in the blood of a patient with suspected typhoid fever who has been inoculated may be of little diagnostic significance unless the titer should increase to 1 500 or 1 000 as the fever progresses. In some non-inoculated individuals who develop typhoid fever, H antibodies may be absent. For this reason it is always well to use O antigen in the tests as well.

Agglutinins against O antigen (somatic antigen) appear in the circulating blood during active typhoid fever even when H agglutinins are not present. They are present in the blood of previously inoculated individuals much less often than are H agglutinins. Their presence in the circulating blood, then, in a titer of 1 200 or 1 500 is highly suggestive of an active infection.

Agglutinins against Vi antigen (Felix and Pitts' antigen) appear in the blood during an active infection with typhoid bacilli but not in inoculated individuals. It is usually unnecessary to include this antigen in the test, since no case of typhoid fever develops Vi agglutinins without developing H or O agglutinins or both. Its principal use is in testing the blood of vaccinated subjects who are suspected of having typhoid fever and who may show H and O agglutinins owing to previous inoculations.

From this brief discussion, it is obvious that the use of both H and O antigens is helpful in the diagnosis of active typhoid fever in both inoculated and non-inoculated patients. Moreover, a single agglutination test may not be sufficient to establish the diagnosis unless the titer of agglutinins is high (1 500) and the patient has not been inoculated.

One is occasionally confronted with the problem of the patient who has fever without localizing signs of infection and in whom the course of the disease is that of typhoid fever. The blood cultures and agglutination tests are negative. The failure to demonstrate agglutinins in the circulating blood may be due to the failure to use both H and O antigens, or the failure to use enough antigens in the typhoid-salmonella group. It is now established that at least twelve distinct serological types of typhoid-salmonella organisms are capable of producing the clinical picture of enteric fever. Therefore, the failure to detect agglutinins to antigens of the typhoid and paratyphoid A or B bacilli in a patient who shows the clinical picture of enteric fever may be due to the fact that the proper antigen has not been used in the test.

There is now convincing evidence that the incidence of typhoid fever can be reduced by means of prophylactic inoculation. That inoculated subjects may develop typhoid fever there is no doubt. This is especially likely to occur if the infecting dose has been large, the exposure frequent and the time between exposure and inoculation has been over three years. There is also suggestive evidence that inoculation of patients with vaccine which is made from strains which fail to contain an adequate amount of O antigen may afford very little protection. When vaccinating, it is well, then, to be sure that the vaccine is prepared from a smooth, virulent strain. At present, the United States Army is using the "Panama 58" strain for the preparation of vaccine rather than the old "Rawling's" strain, since it has been found that the latter has become degraded and often fails to stimulate adequate antibodies as determined by mouse-protection and other tests.

In short, all persons who are living in or plan to visit areas where typhoid fever is prevalent should be vaccinated against it. The vaccination should be repeated every three years, and the vaccine should be prepared from a smooth, virulent strain of organism.

ACUTE FOOD POISONING DUE TO BACTERIAL INVASION OR BACTERIAL PRODUCTS

Every year, especially in the summer months, physicians encounter cases of acute food poisoning resulting from bacterial infection or its products. Experience has shown that these cases are due either to the toxic products of the killed bacteria or to the combined activity of the living bacteria and their toxic products. Poisonous substances which develop as a result of the growth of bacteria in meat or other food may also play a part.

From numerous studies,³ it has been shown that food poisoning is usually caused by the salmonella group of organisms, and in the majority of cases *Salmonella aertrycke* and *S. enteritidis* are the most important. Rarely *S. supestifer* and *Shigella dysenteriae* cause symptoms of acute food poisoning. The foods which are most likely to become infected are meats and fish,—especially when canned,—milk products and, less often, sea food and fruits.

The clinical features of food poisoning are relatively uniform, although they vary greatly in severity and duration. The three cardinal symptoms are abdominal pain, diarrhea and vomiting. The variation in the clinical picture depends on the amount of toxic material ingested and whether or not living bacteria are present as well. In oc-

casual cases, vomiting may be infrequent or absent. In many cases, however, vomiting is very severe and persistent and is the outstanding feature. Indeed, in some epidemics abdominal pain and diarrhea may be entirely absent. In these nausea and vomiting associated with high fever are the conspicuous features.

For purposes of description cases of acute food poisoning may be divided into three groups: cases in which the symptoms are purely those of irritation of the gastrointestinal tract without absorption of any toxic substances; cases in which the symptoms are those of a severe gastroenteritis with constitutional symptoms (fever, prostration, cramps and so forth); and cases in which the constitutional symptoms and signs are more protracted and conspicuous than those of the gastroenteritis.

In the first group the incubation period is short, recovery is rapid and there are no after effects. Fever and prostration are absent.

In the second group the incubation period is about two to four hours after the ingestion of food; the onset is acute and severe, with symptoms of gastroenteritis, and constitutional symptoms such as fever, prostration and muscle cramps, occur. Very often the acute symptoms disappear within twenty-four to thirty-six hours and recovery is rapid. There is evidence supported by animal experimentation that the acute gastroenteritis is due to the local action of the undestroyed toxins, whereas the constitutional symptoms result from their absorption. There is very little to indicate that the symptoms in these cases are due to the ingestion of living bacteria.

In the third group the symptoms are due to infection with living bacteria as well as to toxins. As a rule, the incubation period is not less than twelve to eighteen hours, the initial symptoms are less acute and abrupt, and the constitutional symptoms are much more striking and protracted.

The precise etiologic diagnosis of bacterial food poisoning may be exceedingly difficult in the cases in which the symptoms are due to the effects of the toxin alone. The examination of excreta for living organisms should be carried out in all cases of suspected food poisoning and after a week or more, the examination of the blood for specific agglutinins (*S. aertrycke*, *S. enteritidis*, *S. typhimurium*) may aid in the etiologic diagnosis. Samples of the suspected food should be obtained and sent to laboratories which are equipped to study these infections by means of both culture and animal experimentation.

The prevention of food poisoning may be difficult, but it is perhaps well to recall that in hot

weather all food should be cooked thoroughly, if it is eaten in the cold state, it should be protected from contamination and adequately refrigerated.

Serious infections of the gastrointestinal tract in infants have been described by Schiff¹⁰ as being due to other strains of *Salmonella* such as the "Panama strain." It is important, then, in any case of acute infection of the gastrointestinal tract to study the case from the point of view of *Salmonella* infection.

DYSENTERY

Bacillary dysentery is still a common disease in the summer months of the year in various parts of the United States. The symptoms and signs vary widely so that the recognition of mild cases may be exceedingly difficult, unless the possibility is entertained in all cases of diarrhea and appropriate methods are used for detecting the organism in the stools or for studying the blood for specific agglutinins. In a few cases the symptoms and signs of dysentery are not unlike those of acute food poisoning and blood and mucus fail to appear in the stools in others. The diagnosis is suggested immediately by the presence of mucinousanguineous stools, diarrhea and tenesmus.

The diagnosis of dysentery can be made by isolating the organism from the stools. These should be obtained in their fresh state and cultured as quickly as possible. If there is a delay between the time that the stool is passed and the time it arrives in the laboratory, it is well to preserve it in glycerin, as recommended by Wu and Sia.⁴ Their procedure was to use two parts of 50 per cent glycerin and one part of stool. In this way the stools were preserved so that dysentery bacilli could be isolated from them much more readily than when glycerin was not used.

Within recent years, a great many mild cases of dysentery due to the Sonne strain have been recognized especially in New England. Since the infections due to this organism may be mild, they are frequently overlooked and serve as a source for the spread of the infection. Indeed one of the problems in the control of dysentery is the difficulty in recognizing carriers and mild cases. These sources of infection are frequent and not readily recognized.

Aside from the lesions in the colon, there are other clinical features of bacillary dysentery requiring comment. These are the nonsuppurative complications occurring within fourteen to twenty-one days or longer after the onset of dysentery: arthritis, conjunctivitis and urethritis.

During and following an acute bacillary dysentery, an acute arthritis may be a feature of the illness. Usually it develops during convalescence from the symptoms referable to the intestines, commonly appearing between the tenth and the thirtieth day after the onset of illness. The joints most frequently affected are the knees, hips and those of the hands. With the onset of the arthritis there is fever of indeterminate duration varying from 100 to 102°F, which may continue for three weeks. The local condition of the joints is characterized by pain, tenderness and swelling, limitation of motion and occasional periarticular swelling with involvement of the tendon sheaths. There is normally no redness of the skin, although the surface temperature may be elevated. The fluid is light yellow and slightly turbid, and contains moderate amounts of mucin and between 1000 and 10,000 white blood cells per cubic millimeter, with polymorphonuclear leukocytes predominating. The fluid is invariably sterile, but it may contain agglutinins against the infecting strain of dysentery bacilli. The outlook for complete recovery and normal joint function is excellent, in spite of the fact that symptoms may be severe and continue for as long as two or three months.

Conjunctivitis following dysentery is usually a simple catarrhal inflammation of the conjunctiva, and the exudate never contains dysentery bacilli. The objective signs are conspicuous, and the subjective symptoms may be minimal. In most cases the inflammation subsides after a few days and causes no permanent damage.

The urethritis which has been described by various investigators, especially Schittenhelm and Schlecht,⁹ may occur with the arthritis or with conjunctivitis. It may be difficult to distinguish from the urethritis due to gonococcal infection, which is not infrequently accompanied by conjunctivitis. The diagnosis is based on a history of an acute bacillary dysentery followed by an arthritis of the larger joints, with sterile synovial effusion, from which complete recovery occurs. When the arthritis is accompanied by a conjunctivitis, iritis or urethritis, such as was observed in numerous cases by Schittenhelm and Schlecht during the World War, the discrimination between dysenteric and gonorrheal arthritis may be difficult. The bacteriological examination of the stools and of the urethral secretion, together with the history, should make such a differentiation more certain.

SUIPESTIFER INFECTIONS

Within the last few years there have been an increasing number of reports of infections due to *S. supestifer*, and excellent reviews of the subject

have been made by Harvey,⁶ Kuttner and Zepp⁷ and Cohen, Fink and Gray.⁸ This organism is also known as the bacillus of hog cholera, and for a time, before the true nature of hog cholera was known, it was considered to be the etiologic agent of the disease. The normal habitat of the organism is in swine, but it may produce infection in man by infecting food such as pork, ham, sausage, milk, tapioca pudding, ice cream, crab meat or veal. So far as is known, the organism enters the body via the gastrointestinal tract and produces symptoms of fever without localizing signs of infection, of fever with foci of infection in various organs or of acute food poisoning.

Infections with this organism occur sporadically and not in epidemic form. For this reason, it is frequently impossible to trace the source of infection or to prove that the infection was caused by eating infected food. One is especially likely to observe such cases following surgical operations or during the course of debilitating diseases. Many of the cases described have occurred in children. The mortality increases with age, so that under twenty-five years of age it is about 20 per cent, whereas over twenty-five it is in the neighborhood of 60 per cent.

In from 50 to 60 per cent of cases of infection by *S. supestifer* the outstanding feature of the illness is fever without localizing signs of infection. The diagnosis in such cases is made by isolating the organism from the circulating blood, stools or urine or by detecting specific agglutinins in the circulating blood. In some cases, positive agglutination reactions in the blood do not appear for three to five weeks following the onset of the infection, so that the diagnosis may be missed if repeated tests are not done.

Metastatic foci of infection due to *S. supestifer* organisms are not infrequent following bacteremia.⁶⁻⁹ The common areas involved are the lungs (33 per cent), the joints (15 per cent) and the bones (5 per cent), the respective lesions being pneumonia, arthritis and osteomyelitis. Other less common lesions are pyelonephritis, abscess of the spleen, cholecystitis, meningitis, pericarditis and pleural effusion.

STAPHYLOCOCCAL INFECTIONS

Following the ingestion of food which has become contaminated with *Staphylococcus aureus*, the symptoms of acute food poisoning, namely nausea, vomiting and diarrhea, may occur. These organisms have been isolated from cakes and pastries (filling in chocolate éclairs, cream puffs and so forth), and it has been demonstrated conclusively¹¹ that the acute symptoms are due to the

action of toxins which are produced by the growth of organisms. The infections usually occur in localized outbreaks, and the symptoms begin within a few hours, usually two to three, after the ingestion of the infected food. The diagnosis can be made by isolating staphylococci from the suspected food. Recovery is usually complete, except for rare fatal cases in which abscesses of the intestinal wall occur.¹² It is perhaps well worth remembering that not all strains of *Staph aureus* produce toxin which is capable of causing acute gastroenteritis, so that the mere finding of these organisms in food does not necessarily mean that they are the cause of the infection. A careful search for other organisms should also be made. 818 Harrison Avenue.

CASE RECORDS OF THE MASSACHUSETTS GENERAL HOSPITAL

ANTEMORTEM AND POSTMORTEM RECORDS AS USED
IN WEEKLY CLINICOPATHOLOGICAL EXERCISES

FOUNDED BY RICHARD C. CABOT

TRACY B. MALLORY, M.D., *Editor*

CASE 26031

PRESENTATION OF CASE

First Admission A forty-one-year-old woman was admitted to the hospital complaining of headaches of three months' duration.

Seven years before admission the patient apparently suffered from some form of "shock," which left her with a "paralyzed" left leg and arm for about three months. The left eye was similarly involved in this paralysis, although the exact nature of the involvement could not be determined. There were associated headaches which were made worse by emotional stress and excitement. She recovered from these complaints in three months and was well for over six years until three months before admission when she again experienced generalized headaches and pain behind both eyes, with associated vertigo. These symptoms became worse during times of stress and excitement and were occasionally associated with vomiting.

Physical examination revealed an obese woman in no apparent discomfort who however, complained of intermittent headaches. Examination of the heart, lungs and abdomen was negative. The blood pressure was 100 systolic, 65 diastolic. The pupils were round and regular, but the right was larger than the left, both reacted slightly and sluggishly to light, but equally and actively to accommodation. There was slight choking of both optic disks. The whole left side, that is, the shoulder, elbow, knee and ankle muscle groups, seemed slightly weaker than the right. Orientation, cooperation and memory were apparently normal. Attention was poor. The remainder of the neurological examination was negative.

The temperature, pulse and respirations were normal.

Examination of the blood revealed a red-cell count of 5,500,000 with a hemoglobin of 80 per cent, and a white-cell count of 5500 with 58 per cent polymorphonuclears, the stained smear was normal. The urine was negative. The blood Hinton and Wassermann tests were negative. A lumbar puncture showed an initial pressure of 230 mm of water, which responded well to jugular compression, the total protein was 36 mg per

100 cc, and the sugar 65.3 mg, the fluid contained 3 lymphocytes per cubic millimeter, and the Wassermann and gold-sol tests were negative. Roentgenograms of the skull were negative. An encephalogram was unsatisfactory.

The patient remained in the hospital for about three weeks for observation. Her headaches persisted. She was discharged unimproved.

Second Admission (two months later) It was stated that the history was almost of negligible value because of language and "mental" difficulties. It was thought that she probably had had constant headaches since her discharge. She had non-projectile vomiting a few times, and was admitted because of a continuation of the symptoms noted on her first admission. Her physical and neurological examinations were unchanged except that there was a bilateral papilledema of 3 diopters, with engorged retinal arteries and veins but no hemorrhages. Her temperature, pulse and respirations were normal, and the blood pressure was 146 systolic, 90 diastolic. Roentgenograms of the nasal sinuses and skull were essentially negative.

On the fourth hospital day a right subtemporal decompression was performed under Avertin-ether anesthesia. The dura was tense, and when it was incised crucially, the brain herniated considerably. There was no local evidence of tumor, but the cortical vessels were unusually large and tortuous and seemed more numerous than under normal conditions. No exploration below the surface was made. The dura was not closed; no bone was replaced, the wound was closed in layers, with the decompression area well filled. She had an uneventful convalescence, seemed somewhat improved and was discharged on the twenty-first postoperative day to be followed in the Out Patient Department.

Six months later she complained of pain in the top and back of the head. The decompression area bulged moderately but was not tense. There was a slight left central facial weakness, and the knee jerks were active, the left greater than the right. There were no other positive findings. She failed to report to the clinic thereafter until she was readmitted to the hospital.

Third Admission (four years later) She complained of periodic exacerbations of headaches in the region of the operative defect, associated with dizziness, vomiting and dimness of vision. These episodes occurred every four to fifteen days and lasted a few days. The physical, laboratory and neurological examinations were negative. The optic disks showed no atrophy or papilledema. The decompression wound was tense but did not

pulsate or bulge. A lumbar puncture showed an initial pressure of 220 mm of water, which rose to 400 mm with jugular compression. On removing 2 cc. of spinal fluid the pressure fell to 190 mm., and after 12 cc had been removed it was 90 mm. The fluid was clear and colorless and was negative to routine tests. The decompression wound was softer after the lumbar puncture. She was discharged on the seventh hospital day.

Fourth Admission (two years later). She came into the hospital because of vague generalized back and abdominal pains. The physical and neurological examinations were negative, except that her heart was slightly enlarged by x-ray and her blood pressure was 162 systolic, 100 diastolic. Roentgenograms of the dorsal spine showed changes consistent with those of a hypertrophic arthritis, skull plates were negative. She was discharged on the sixteenth hospital day with her condition unchanged.

Final Admission (two years later, fifteen years after her first shock). Two hours before her admission the patient was found unconscious on the floor. She had complained of numbness in the fingers the morning before entry. She was busy in the kitchen when, unobserved, she collapsed. Physical examination showed an obese, cyanotic and comatose woman breathing stertorously. The pupils were small but reacted to light. The fundi showed slight papilledema, with hemorrhages and pigmentation. The soft tissues below the old decompression wound were bulging and seemed under considerable tension. No movement of any extremity was noted but the reflexes were depressed. There was no Babinski sign, nor stiff neck. There were numerous coarse rales in the chest, and peripheral edema. Because of the stertorous breathing the heart sounds could not be heard. The blood pressure was 100 systolic, 60 diastolic. The patient failed rapidly and tracheal rhonchi appeared. The coma persisted and the temperature rose to 104°F., with increasing pulse and respirations. The systolic blood pressure dropped to 50, and she died about twenty hours after entry. No lumbar puncture was done but a needle was inserted into the bulging old craniotomy wound without result.

DIFFERENTIAL DIAGNOSIS

DR HENRY R. VIETS. This complicated case—and I think it must be complicated and undiagnosable because I have even been given the complete hospital record to read—began when the patient was thirty-four with paralysis lasting three months on the left side, presumably due to a right-sided brain lesion, which was probably on a vas-

cular basis. Seven years later she came in and there was still evidence of weakness on the left side, but no true hemiparesis or hemiplegia. She had begun to show signs of increased intracranial pressure and we find that there was some confirmatory evidence on lumbar puncture. The initial pressure was 230 mm of water otherwise the cerebrospinal fluid was negative. X-ray study did not help in the diagnosis; the encephalograms, unfortunately, were unsatisfactory. The latter might have been of help in throwing some light on the nature of the lesion. One presumes that the diagnosis of a brain tumor, a right-sided lesion in the parietal region, was suspected, but there was not enough evidence to justify operation.

She came in again within two months with more symptoms: constant headache and bilateral papilledema of 3 diopters, with engorgement of the retinal arteries. The diagnosis seems clearer than ever of increased intracranial pressure on a neoplastic basis but again the lesion did not appear to the physicians in the hospital to be local. They did subtemporal decompression. The vessels were unusually large and tortuous and seemed more numerous than normal. In spite of the fact that the surgeons were looking through an opening not much larger than a silver dollar, an abnormality of the blood vessels on that side was observed. That is the side on which one would suspect the lesion to be.

She improved but six months later was seen in the Out Patient Department with a bulging of the decompression and a little evidence of left facial paralysis; the reflexes were somewhat greater on the left side. In other words, the lesion was presumably increasing in size, or the findings were the result of operative interference.

Four years later she came back with more headaches, but this time she also had dizziness, vomiting and dimness of vision. They found no increased pressure by ophthalmoscopic examination and no atrophy of the disks. The decompression was tense, and the lumbar puncture still showed increased pressure (220 mm.) the decompression wound was softened as a result of the lumbar puncture. All we can say is that we continue to think that she had an intracranial lesion which resulted in increased intracranial pressure. We do not know anything more about its character or exact localization. At this period of observation there was presumably a decrease in the intracranial pressure, and one is inclined to state that the lesion was probably not a growing neoplasm. A new growth would have continued to increase the pressure but something had happened and the symptoms had definitely decreased.

in intensity. Then we turn back to the operation and recall the changes in the blood vessels. We begin to consider the possibility of a blood-vessel tumor rather than a solid neoplasm, such as meningioma or glioma.

On the fourth admission we have a little additional evidence that helps—provided the diagnosis of a blood-vessel tumor is ultimately going to prove to be correct—in that the heart had become enlarged. It is known that certain types of angiomas increase blood flow and may lead to secondary enlargement of the heart.

By the time of the final admission she had become extremely ill and died shortly after entry. Nothing from the record helps much except that she had had some sort of unconscious attack, had fallen on the floor, had gone into coma and died. The neurological examination did not throw any additional light on the diagnosis.

We have then, in summary, a patient whose symptoms began at thirty-four and who died at forty-nine. There is evidence that she had intracranial disease, and there is some evidence that the intracranial disease was on the right side of the brain in the parietal region. Evidence of increased intracranial pressure was present at times, and this pressure was only slightly, if at all, increased at other times. The course varied and was not definitely progressive; it was certainly not one that is usually associated with an ordinary type of brain tumor.

It seems likely that in spite of the five admissions to the hospital a definite clinical diagnosis was not made. Even from going over the record here, one gets the impression that no diagnosis can be made. It is presumptive of me to suggest a diagnosis, but I think I shall, in view of the fact that we ought to reach some conclusion even if we are wrong. I think that the patient had an angioma of some type.

There are a number of kinds of angioma. The commonest type perhaps is a hemangioma or an angioblastoma, which is usually in the cerebellum and not in the cerebrum. This is a true tumor, presumably the type described by Lindau,¹ associated with cysts in the cerebellum and occasionally in the cerebrum and with von Hippel's disease of the eye, cysts in the pancreas and so forth. That type of blood-vessel tumor is fairly well known, and we have had a number of examples here in the hospital. It is my belief that this patient did not have a true hemangioma, largely because of the facts that this type of tumor is familial and hereditary, that it practically always begins in the cerebellum and that it is associated with cysts and hemangiomas of the eye and elsewhere.

There are two other possibilities of angiomatous tumors. One is the cavernous hemangioma. This is quite possible here. I am not sure that it is the best choice. It usually does not have any definite connection with the meninges, being situated in the white matter, and consists of tumors of the blood vessels themselves, which tend to form cysts. I should rather favor a third type of tumor—an angiomatous malformation or congenital angioma.

If this diagnosis proves correct, is the lesion primarily venous or arterial or both? If it were venous one would not expect choked disks. Furthermore, ordinary venous angiomas of the brain are commonly associated with facial nevi and other venous changes in the skin which this patient did not have, so far as the record goes. In addition, they are often associated with epilepsy, which this patient did not have, unless the first "shock" was an epileptic attack, and are not often complicated by cardiac hypertrophy. A better diagnosis would perhaps be an unusual type of congenital malformation of the arteries of the brain which is ordinarily associated with choked disks. This type of tumor causes secondary cardiac hypertrophy, there may even be enlargement of the aorta. But we miss one very important point here, if the diagnosis is correct—there is no description of a bruit. A bruit should be heard in most cases of this rare type of angiomatous tumor, but it may not even have been listened for. If one had been noted it would have helped enormously in diagnosis. Also, increased vascularity of the skull was not mentioned—that too would have helped.

I am very doubtful about the diagnosis, but I should think that my best guess would be that, because of the duration of the symptoms, the remissions and the observations at the time of the decompression, this is an angiomatous tumor. This congenital type of angioma is confined, at least in part, to the right side of the brain and is more likely to be arterial than venous.

I should not be a bit surprised if some other diagnosis were made by the pathologist. What could it be? A slowly growing meningioma seems unlikely on account of the course. I think it might be a rare type, possibly a slowly growing glioma, with hemorrhage into it to begin the long train of symptoms. This seems less likely to me than a vascular tumor, therefore I shall stick to congenital hemangioma.

DR TRACY B MALLORY. Dr Ayer, would you like to comment?

DR JAMES B AYER. I hoped you would not call on me in this difficult case. I did not know the patient, and I do not know the diagnosis. Obviously we must be dealing with an intracranial

lesion producing an intermittent course over a period of fifteen years. There are very few tumors that can do this, although slowly growing ones have been shown to run a period even longer. Dr. Viets has elected one that may so act. I also suggest the possibility of a cholesteatoma, which may run a long course with intermittently progressive symptoms. Aside from tumors, we should not forget collections of cerebrospinal fluid which go under various names—serous meningitis, edema and so forth—and which not infrequently give a high degree of choked disks and symptoms of brain tumor, frequently without localizing signs. A group of these cases has been described by Dandy, some improved with decompression, others without. Putting the whole case together, I should agree that Dr. Viets has picked the most plausible diagnosis.

DR. WYMAN RICHARDSON: Would one not have to consider simple aneurysm at the base of the brain?

DR. MALLORY: Do you care to answer that, Dr. Viets?

DR. VIETS: There is no evidence that she had bleeding into the cerebrospinal fluid or any involvement of the extraocular muscles or nerves which are common in aneurysm. An aneurysm is, of course, a possibility, but the choking of the disks and the receding of the choking are against the diagnosis. She did not have any sudden episode except the final one.

DR. RICHARDSON: The first episode was sudden.

DR. VIETS: Possibly provided the history is accurate. After all these blood vessel tumors and aneurysms are difficult to differentiate, not only clinically but even pathologically.

CLINICAL DIAGNOSES

Cerebral hemorrhage.
Bronchopneumonia
Pulmonary edema

DR. VIETS'S DIAGNOSES

Brain tumor: angiomatous malformation
Cardiac hypertrophy: secondary

ANATOMICAL DIAGNOSIS

Cavernous hemangioma, probably congenital

PATHOLOGICAL DISCUSSION

DR. CHARLES S. KUBIK: I congratulate Dr. Viets. We did not suppose when this case was selected for discussion that anybody would be likely to make a correct diagnosis, but thought it ought to be taken up because the patient had been observed for a long time and presented an inter-

esting and puzzling clinical picture. As Dr. Ayer has said, we see cases every now and again of increased intracranial pressure with spontaneous remission of symptoms in which the diagnosis remains doubtful. Here we have an example of one condition which can behave in that way.

At autopsy there was a cavity filled with about 25 cc. of brownish red hemorrhagic fluid outside the dura at the site of the old right temporal exploration. Microscopical examination disclosed an angiomatous formation of large thin walled blood vessels, with old and recent hemorrhages in the surrounding tissues. There were also small clusters of similar vessels in the subarachnoid space in other places, and most of the superficial cerebral veins were enlarged and tortuous. There was old hemorrhage in one of these angiomatous lesions situated in the left Sylvian fissure. There were numerous connecting branches between the abnormal vessels and veins, but no connection with arteries could be demonstrated. I should suppose that these lesions represent developmental anomalies and not true neoplasms. They may increase in size some what through enlargement of existing small vessels, which are usually very numerous. Hemorrhages probably explain the acute episodes.

DR. VIETS: Was there any hypertrophy of the heart or aorta?

DR. KUBIK: The autopsy was restricted to the head.

CASE 26052

PRESENTATION OF CASE

A sixty-four-year-old businessman was admitted complaining of regurgitation of food.

Ten years before entry after eating fish chowder, the patient became ill for a period of three days with nausea and vomiting. Ever since he had been troubled by a varying degree of regurgitation of liquids and less frequently of solid foods. This generally occurred at night after he had been in bed for two or three hours and rarely occurred during the day. Fluid always came up easily without nausea or effort and did not seem to come from the stomach. There was no blood. Regurgitation consisted of about a mouthful at a time and gradually progressed to the point where it occurred each night but caused no outstanding discomfort. Four or five years before entry he undertook a course of physical exercise, Swedish massage and self-imposed diet which caused his weight to decrease from 193 to 174 pounds. These meas-

ures had been adopted because the patient had felt under par and had been quite dyspneic with exertion. Subsequently he was very much relieved, although the regurgitation continued. One year before entry he had a slight cough productive of watery sputum. Although the acute phase persisted for only two or three days the productive cough continued throughout the entire winter. Four months before entry he contracted another cold and discovered that he had lost about 15 pounds during the preceding month. Regurgitation became slightly more frequent, and he developed a cough productive of about a pint of watery frothy sputum daily. There was never any blood or grossly purulent or fetid material in the sputum. At about that time there was an afternoon rise in temperature to 100 or 101°F, and both the cough and fever continued until entry. There was some constipation, and the patient was troubled by hemorrhoids. His appetite became quite poor. Cold liquids caused immediate regurgitation, but hot liquids did not. He frequently regurgitated brownish salty liquid in the morning on waking. Two months before entry he was confined to bed for four weeks because of afternoon fever and a physician told him there was consolidation of the left lower lobe, which cleared up in a week or two. Associated with this illness during the few months before entry there was some hoarseness, which varied in intensity, and the cough gradually became brassy in character. X-ray examination four and a half months before entry showed a soft-tissue mass behind the middle portion of the heart in the posterior mediastinum. This was almost round in shape and produced a pressure defect in the medial aspect of the lower esophagus, which was adherent to the mass. Barium entered the region of this mass through a 2-cm opening from the esophagus and filled a fairly round cavity, within which were large filling defects, particularly at its lower posterior portion. Some of the barium flowed from this cavity into a more irregular one in the lateral part of the soft-tissue mass, and from there, small quantities trickled through a minute opening into one of the minor bronchi of the left lower lobe. The remainder of the gastrointestinal tract showed no evidence of disease. There was no obstruction in the esophagus. Examination of the chest showed normal diaphragmatic position and movement. There was incomplete aeration in the medial part of the left lower lobe, and some questionable dilatation of the bronchi in this region. There was no shift of the mediastinum.

Physical examination showed a well-developed but poorly nourished man who appeared to have

lost considerable weight. Examination of the mouth and pharynx was negative. There was slight pallor of the mucous membranes. The maximum apex impulse of the heart appeared to be slightly displaced toward the midline, although the position was not stated. The sounds were regular and of good quality. No murmurs were heard. The blood pressure was 105 systolic, 60 diastolic. The lungs were clear and resonant anteriorly. In the lower third of the left chest posteriorly there were fine crepitant rales and slight dullness with moderate diminution in intensity of the breath sounds.

The temperature was 97.6°F, the pulse 104, and the respirations 32.

Examination of the urine was negative. The blood showed a red-cell count of 4,600,000 with a hemoglobin of 70 per cent, and a white-cell count of 14,500 with 83 per cent polymorphonuclears. A single sputum specimen was copious, thin and watery, no blood was present, and examination for tubercle bacilli was negative. Several stool specimens gave negative reactions to the guaiac test. A blood Hinton test was negative.

X-ray examination showed that the soft-tissue mass previously described in the lower end of the esophagus had slightly increased in size. Ulceration within it had extended considerably and reached almost to its lateral wall. The cavity was connected with the lower end of the esophagus, but no barium could be observed to enter into the bronchial tree. The pressure defect in the esophagus was more marked, and there was delay, but no definite stenosis, at the lower end of the esophagus. The appearance of the left lower lung field had not changed appreciably since the last observation.

During the patient's stay in the hospital he remained afebrile and moderately comfortable. Each day he brought up 200 to 300 cc of thin watery, frothy sputum, which at times was slightly blood tinged. He had no pain. While in the hospital, pneumothorax was produced artificially in the left pleural cavity, and on four occasions 400, 600, 800 and 700 cc of air were introduced. The intrapleural pressure remained negative. The patient's sputum decreased considerably in amount after this, and he seemed to cough much less.

After discharge from the hospital the patient's condition gradually grew worse, with brief periods of temporary improvement. His cough increased in frequency and productivity, and he lost strength and appetite. He continued to be able to get down a fair amount of liquid food, however, although he vomited about twice daily. The vomitus consisted of watery material and

mucus but no occult blood and varied from a quart to a quart and a half in amount. His weight decreased about 2 to 4 pounds each week and, at the time of his death, had dropped to about 70 pounds. For two months he was unable to rise from bed and for the last two weeks unable to swallow anything. He died five and a half months after his discharge, about ten and a half years after the onset of his illness.

DIFFERENTIAL DIAGNOSIS

DR. ALLEN G. BRAILEY The diagnostic problem in this case has to do with the nature of the mediastinal mass. The earliest symptom which may have been related to this mass was regurgitation which began ten years before entry, when the patient was fifty-four years old and which persisted to the end. The next symptom which may throw light on the nature of the mass was slight cough, which began one year before entry. Then four months before entry, the patient discovered that he had lost 15 pounds of weight and that he had a little fever. He became constipated and lost his appetite. From then on his course was steadily downhill. In the hospital he was found to have consolidation of the lower lobe of the left lung which was promptly explained by the demonstration of a fistulous tract between the lower esophagus and the left lower bronchus.

Fistulas between the esophagus and a bronchus or the esophagus and the trachea are usually due to carcinoma. Less often they are caused by tuberculosis and rarely they represent minor developmental defects, not incompatible with life. In this case there was no evidence of fistula prior to one year before death and nothing to suggest tuberculosis. Apparently the sputum was examined only once for tubercle bacilli; none were found and I think there is very little likelihood that this fistulous tract was due to tuberculosis. On the other hand his progressive downhill course, his rapid loss of weight and the ragged, irregular appearance of the tract by x-ray are at least consistent with the symptoms and signs of neoplasm. I believe this fistula extended through cancer tissue and that the cancer probably arose at the esophageal end where the bulk of the abnormal tissue is shown by x-ray to be situated.

While it seems impossible not to believe that this man had a cancer nevertheless there are some serious objections to this diagnosis. It does not satisfactorily explain the whole of this ten year period of disability, for it is not credible that he could have had a cancer of the esophagus ten years before entry to the hospital of sufficient size to cause regurgitation and yet have remained in

essentially good health until a few months before death. We are furnished with the suggestion that this difficulty with regurgitation began shortly after a meal of fish chowder. There may be fishbones in fish chowder and one may have lodged in his esophagus. So far as I can find, one of three things may happen to a fishbone so lodged. It may dislodge itself and go on into the stomach. Or it may require removal by esophagoscopy. Or it may penetrate the esophagus and set up an acute mediastinitis. But it could never cause the chronic symptoms of mild obstruction such as occurred here over a nine year period. Partial stricture of the esophagus could have caused this long history of regurgitation and have provided the nidus for the later development of cancer. This is a real possibility and I cannot rule it out, but it is subject to the objection that we know of no cause for such a stricture, such as the swallowing of caustics. If it was a congenital stricture why did he have no symptoms prior to fifty years of age?

There remains another possibility, namely that the patient may have had a diverticulum of the esophagus. On studying the x-ray plates it is easy to follow a rounded outline which would do very well for the as yet undestroyed wall of a large diverticulum. A diverticulum of this size is undoubtedly a pulsion diverticulum since traction diverticula (caused by adhesion with tuberculous lymph nodes) are usually only a few millimeters deep. Those of the pulsion variety are much commoner in the upper esophagus at its junction with the hypopharynx. Their etiology is not wholly settled, but it is thought that they develop at points of congenital weakness in the muscular wall through which the esophageal *mucosa* gradually pouches outward. They may enlarge very slowly, and they cause no symptoms until they become so large and empty so poorly that they kink or distort the esophagus. Such kinking pulls the mouth of the diverticulum more and more into line with the esophageal lumen and causes the pouch to fill with increasing ease. Its pull and pressure help to close off the lower portion of the esophagus, and symptoms of obstruction with the regurgitation of recently swallowed food appear.

In conclusion then I think that this patient died of carcinoma of the esophagus which had communicated with the left lower bronchus and set up a chronic pneumonitis of the left lower lobe. It is at least a reasonable hypothesis that this cancer arose in an esophageal diverticulum which he had had for years and which had caused symptoms for about ten years.

DR AUBREY O HAMPTON I can add nothing to the x-ray description Dr Brailey has made the same interpretation on the x-ray films as we did Stricture of the esophagus is ruled out by the absence of obstruction to the flow of barium Food particles in a diverticulum can also be ruled out because the filling defect did not shift in position or change much in shape The small fistulous tract demonstrated at the first examination is seen on only one or two of the films Only a very thin, thread-like stream of barium passed into one or two of the smaller bronchi, and this was not present on the second examination The opening from the esophagus into the large rounded cavity is quite typical of that of a diverticulum

CLINICAL DIAGNOSIS

Carcinoma arising in diverticulum of esophagus

DR. BRAILEY'S DIAGNOSES

Carcinoma of esophageal diverticulum, with invasion of left lower bronchus
Tracheobronchial fistula
Chronic pneumonitis

ANATOMICAL DIAGNOSES

Epidermoid carcinoma of diverticulum of the esophagus, with invasion of hilus of left lung
Esophageal obstruction
Emaciation
Bronchiectasis, right lower lobe, slight
Pulmonary atelectasis
Pericarditis, acute fibrinous, localized
Pleuritis, acute fibrinous, localized

PATHOLOGICAL DISCUSSION

DR TRACY B MALLORY The autopsy findings bear out almost point for point Dr Brailey's predictions We found a large diverticulum of the

lower end of the esophagus communicating, through a perfectly smooth opening, with an otherwise normal esophagus Some little distance from its mouth the walls of the diverticulum became granular, thick and indurated, obviously carcinomatous Anteriorly the tumor had spread by direct extension into the hilus of the left lung We were unable at autopsy to demonstrate the bronchial fistula, but the history definitely suggests that this closed some time before his death The bronchi of the left lower lobe showed moderate but not great dilatation and only moderate inflammatory reaction I think we must make a diagnosis of bronchiectasis, but I do not believe that the cupfuls of watery sputum which the history mentions could have been raised from these bronchi and it is more probable that the "sputum" represented discharge from the diverticulum through the fistula

Another point of interest is the question of esophageal obstruction It is quite clear from the history, as Dr Brailey pointed out, that for many years after the onset of symptoms of regurgitation there was no obstruction This only developed in the last year of life One might easily have guessed that it resulted from extension of the carcinoma to the esophagus proper This was not the case, however, and the obstruction must have been due either to external pressure or to kinking, as Dr Brailey suggested

The tumor was a remarkably well-differentiated, very slowly growing epidermoid carcinoma, certainly not above Grade I in malignancy It is probable that it had been present much longer than the acute symptoms would indicate Despite its extension into the hilar tissues it had not metastasized even to the regional bronchial and mediastinal nodes

Except for incipient terminal pericarditis and pleuritis there were no other anatomical findings of significance

MASSACHUSETTS PUBLIC HEALTH ASSOCIATION

At the call of Dr. Lemuel F. Woodward, then chairman of the Worcester Board of Health, thirty five men representing the State Board of Health and twenty four local boards gathered at the old Revere House in Boston, on January 11, 1890, and officially organized the Massachusetts Association of Boards of Health. They elected as their first president Dr. Henry P. Walcott, chairman of the State Board of Health, and as first vice-president Dr. Samuel H. Durgin, chairman of the Boston Department of Health. This was the second state association formed in America, New Jersey being first, and its fiftieth anniversary, to be celebrated on January 27, is a significant occasion.

The date, 1890, in many respects marks the division between the old and the new in public-health practice. Bacteriology had become a well-established

science with its several specialized applications in medicine, sanitation, agriculture and industry, the causes of many of the important epidemic diseases had been discovered, the basic principles of immunity were being formulated, and the bacteriology of water, sewage and milk was being developed. The Massachusetts Drainage Commission, consisting of such men as Hiram F. Mills, William T. Sedgwick, Thomas M. Drown, Allen Hazen and Edwin O. Jordan, was particularly influential in this latter field, while at the Massachusetts Institute of Technology some of the earliest work on the bacteriology of milk was being done.

It was, therefore, most fitting that at just this time a few people with vision saw the value and importance of forming an association of persons engaged in public health work who could discuss together matters of sanitary interest, who would formulate and enforce legislation, and who could, through their professional relations, come to know one another and to exchange ideas regarding the mutual problems they met as local health officers or board members.

The association soon invited persons of less exclusive administrative interests but of a wide training and vision to join with them, and the early roster of membership included Charles V. Chapin, Samuel C. Prescott, C. E. A. Winslow, George C. Whipple, Dr. Theobald Smith, Dr. Hibbert W. Hill, Dr. Milton J. Rosenau and others whose names are well known in the annals of public health progress. These men brought to the meetings a breadth of scientific knowledge and training which immediately gave progressive leadership to the group.

Each important forward step in public health during the past fifty years gained impetus through the meetings of the association. The subjects considered dealt with live current problems, and the speakers were usually leaders in their fields. One can trace in the proceedings the campaign for safe milk, including the early work done on bacteriological examination, epidemiological studies proving the importance of milk in the spreading of disease, the practice of pasteurization and the supporting legislation to bring about more ade-

quate milk control Professor Sedgwick was the leader in these discussions, ably supported by Dr Smith and Chapin Every step in the control of diphtheria, from the value of laboratory examinations as aids in diagnosis to the most recent immunization practices, is reflected in the records Without the medium of the association for discussing and urging the successive steps in the use of antitoxin and in active immunization with toxin-antitoxin mixtures and then toxoid, we may fairly assume that there would have been more lag between knowledge and application Chapin's advanced thinking on the importance of contact infection and the uselessness of terminal fumigation is apparent in the records "It is personal rather than municipal cleanliness that health officers must teach," he insisted

The association began the publication of a quarterly journal, known as the *Journal of the Massachusetts Association of Boards of Health*, in 1901 This daring and ambitious undertaking was justified, for it was the parent of the present *American Journal of Public Health*, the official organ of the American Public Health Association The transfer took place in a series of steps and was completed in 1911, when the name of the state association disappeared from the title Dr Hill and Burt R Rickards were the first managers and editors of the journal, and Rickards continued for five years as managing editor of what was then called the *Journal of the American Public Health Association*

The first twenty-five years of the history are the most spectacular because of the extraordinary events that were happening in the field of public health However, the association has continued to have the same general significance down to the present time In 1933, a new constitution was drawn up by a committee of which Dr George H Bigelow was chairman The reorganization provided for three sections a health-officers' section, a laboratory section and a child-hygiene section In 1936, the name was changed to the more appropriate Massachusetts Public Health Association

The association will undoubtedly accomplish as much during the next fifty years as it has in the past fifty years There is still much to be done in

advancing the well-being and comfort of the people and in preventing and alleviating sickness The more spectacular things may have been achieved, but there remains the necessity of eternal vigilance in all measures concerning sanitation and preventive medicine, and there is the same call for leadership and co-operation as there was in 1890

COMMUNITY FUND CAMPAIGN

Most local physicians are well acquainted with the vital community services that are made possible by Greater Boston's Community Fund They know that the various agencies supported by the Community Fund carry on work for humanity which must be done—and that if this work is to be accomplished the annual campaign must be successful

It is significant that every year the scope of the Fund has broadened In 1940 more than one hundred and seventy-five hospitals and health and social-service agencies will have Community Fund support, as compared with one hundred and fifty last year, and the campaign will cover Boston and forty-five surrounding cities and towns

The 1940 goal is \$4,625,000 Though this is \$125,000 more than has ever before been raised, it represents the absolute minimum required to carry on the vital human services through the year In order to attain—and, if possible, to exceed—this goal, the time and effort of more than sixteen thousand unpaid volunteer workers have been enlisted Among them are leading business and professional men and women from all walks of community life

The 1940 quota for the Physicians' Group is \$21,000 Since the 1940 goal, however, is set to meet only the barest minimum requirements, every quota must be oversubscribed The physicians have regularly done more than their share in the past and, with their first-hand knowledge of human needs, they will probably repeat during this campaign, which extends from January 22 through February 6

Chairman of the Physicians' Group is Dr Theodore L Badger He is assisted by the following vice-chairmen Dr Perry C Baird, Jr, Dr Ran-

dolph K. Byers, Dr Earle M. Chapman, Dr E. Stanley Emery, Jr., Dr Thomas H. Ham, Dr Alfred O. Ludwig, Dr Archie A. Abrams, Dr Lendon Snedeker, Dr William B. Stevens and Dr Conrad Wesselhoeft. It is also of interest that a member of the medical profession, Dr Thomas R. Goethals, is the 1940 chairman of the Professional Division.

The theme of the 1940 Community Fund Campaign is built around the life and ideals of Abraham Lincoln, which were typical of this great enterprise by the people and "for the people" of Greater Boston. Its purpose is to teach hope to all, despair to none of the three hundred thousand people who need help each year. The fullest support of all physicians and other public spirited men and women in Greater Boston is vital to the 1940 Community Fund Campaign.

MEDICAL EPONYM

ARTIUS PIENOXENON

Maurice Arthus read a paper at a meeting of the Biological Society in Marseilles on June 16, 1903, entitled "Injections Répétées de Sérum de Cheval chez le Lapin [Repeated Injections of Horse Serum in the Rabbit]." This was published in the *Comptes rendus hebdomadaires des séances et mémoires de la Société de biologie* (55: 817-820, 1903). The translation of a portion of the paper is as follows:

If sterile horse serum (our experiments were made with antitoxic serums) is injected under the skin, into the peritoneum or into the veins of a rabbit, whether the serum be fresh or preserved heated to 57 C. or not heated, no primary or late injury will be produced. Horse serum is not toxic for rabbits. If after an interval of a few days this injection of horse serum is repeated, one may state that after several injections, it will produce, even in small doses, injuries which are mild or severe according to the degree of preparation of the animal and which according to the route of introduction, may be either local or general immediate or delayed. Horse serum is toxic for rabbits which have been rendered anaphylactic by and to horse serum.

Does the human being develop a similar anaphylactic state with local or general injuries similar to those described in the rabbit, under the influence of repeated injections of serum?

Quoting instances of apparent reactions of this type in human beings, the author concludes that such a state does exist, a conclusion which the observations of others have confirmed.

FATAL PUERPERAL SEPSIS FOLLOWING FORCEPS DELIVERY

Mrs. J. B., a twenty-seven year-old primipara, was admitted to the hospital February 1, 1912, in active labor. The expected date of confinement was February 8, the last menstrual period having ceased May 1, 1911. The past and family histories were not recorded.

Examination on entry revealed a vertex presentation in an ODP position. The pelvic measurements were normal. The head was engaged. The temperature was 98°F., and the pulse 80.

After nineteen hours of labor the cervix became fully dilated. Because of lack of further progress a forceps delivery was performed. The patient was anesthetized with ether. After manual rotation of the baby's head, the forceps was applied as for an ODA position. Moderate difficulty was experienced in pulling the head down onto the perineum. Although the color of the baby was normal at birth, it did not breathe and all attempts at resuscitation failed. The mother's condition after delivery was excellent. A one degree laceration of the perineum was sutured with silk worm gut.

On February 4, forty hours after delivery the patient's temperature rose to 102.8°F., and the pulse to 120. The temperature remained elevated throughout the day and at 9 p.m. the pulse rate was 130. There were marked tenderness and spasm on both sides of the uterus. An intrauterine douche of salt solution was given, followed by one of alcohol. She was placed in Fowler's position and ice-caps were applied to the lower abdomen.

The following day the patient's general condition was definitely worse. There were marked tenderness and spasm throughout the lower abdomen. Distention was somewhat relieved by enemas, turpentine stupes and flaxseed poultices.

The patient rapidly failed. Abdominal distention increased, and there was suggestive intra-abdominal fluid. The pulse rose to 160, and the respirations to 50. A throat culture revealed streptococci and staphylococci. Uterine and blood cultures were not taken. She lapsed into coma and

A series of selected case histories by members of the section will be published weekly. Comments and questions by subscribers are solicited and will be discussed by members of the section.

died on the tenth postpartum day. An autopsy was not obtained. The discharge diagnoses were streptococcal tonsillitis, general peritonitis and septicemia.

Comment This septic case is characteristic of those which occur during hospital epidemics. Only one patient of the next five who were delivered escaped the infection, and one of these, the fifth, also died. Strict isolation is the only way to treat this type of puerperal infection. If this cannot be obtained, further admissions to the hospital should be canceled.

The routine treatment in 1912 was intrauterine douches, with or without curettage. In this case no curettage was performed. Douches have no effect on a generalized infection, and they are never used today. It is perfectly possible that, if sulfanilamide had been known and used, this patient might not have succumbed.

ANNUAL PRIZE FOR INTERNS

The attention of interns in Massachusetts hospitals is called to the fact that a prize of \$50.00 has been offered by the Massachusetts Medical Society for the best written and most comprehensive case report submitted by one of their number holding an internship in any Massachusetts hospital which is approved by the American Medical Association for intern training during 1938-1940.

This report is to be typewritten, and when completed is to be sealed, unsigned, in a plain envelope, which in turn is to be placed together with a separate slip bearing the name and address of the contestant, in a larger envelope, and sent to Committee on Medical Education and Medical Diplomas, Massachusetts Medical Society, 8 Fenway, Boston.

The contest this year closes May 5, 1940. Reports may be submitted at any time prior to that date.

DEATHS

BERRY—CHARLES F. BERRY, M.D., of Boston, died October 10, 1939. He was in his sixty-ninth year.

Dr. Berry received degrees from the College of Physicians and Surgeons, Boston, in 1899 and from the College of Physicians and Surgeons, Baltimore, in 1910. He was a member of the Massachusetts Medical Society and the American Medical Association.

LOBO—JOSE P. LOBO, M.D., of Providence, Rhode Island, died November 28, 1939. He was in his sixty-third year.

Dr. Lobo received his degree from the Universidade de Lisboa Faculdade de Medicina, Portugal, in 1900.

He was a fellow of the Massachusetts Medical Society and the American Medical Association.

NEW HAMPSHIRE MEDICAL SOCIETY

DEATH

LAKE—ELMER E. LAKE, M.D., of Hampstead, died at his home on December 6, 1939. Dr. Lake had practiced in Hampstead for forty-seven years.

He was born in East Haverhill, Massachusetts, December 10, 1861, the son of Morris and Eunice (Duff) Lake, and was graduated from the University of Vermont in

1892. During the World War he served as medical examiner at Fort Preble, Maine, at Camp Eustis, Virginia, at Freeport, Maine, and at Fort Williams, Maine, being promoted to a captaincy in February, 1918, which commission he held at the time of his death.

Dr. Lake was a member of the New Hampshire Medical Society and the Rockingham County Medical Society.

He is survived by his widow, Mrs. Mary E. Lake, two sons, Albert C. Lake, of Hampstead, and Morris E. Lake, of Montpelier, Vermont, and a daughter, Mrs. Eunice Sharpe, of Salem, Massachusetts.

HENRY H. AMSDEN, *Necrologist*

MISCELLANY

GENITAL TUBERCULOSIS

Tuberculosis in the male genital organs is believed to be secondary to some other tuberculous focus in the body, most commonly in the lung. Though the prognosis is discouraging and the treatment far from satisfactory, much progress has been made in this field in recent years. Miller and Lustok published a paper (*Genital Tuberculosis* J A M A 113 1388-1394, 1939) based on their observations of 61 male patients with genital tuberculosis, an abstract of which follows.

* * *

At the Sanatorium of the Jewish Consumptives Relief Society, 61 (47 per cent) of 1316 male patients admitted in an eleven year period had genital tuberculosis.

Genital tuberculosis may occur at any age but the vast majority of patients range from twenty to forty years. The younger the patient the more virulent the infection. Genital tuberculosis is secondary to some other tuberculous focus in the body, usually the lungs. Ninety-five per cent of these patients had associated far-advanced pulmonary tuberculosis and 87 per cent had sputum with tubercle bacilli. The infection may reach the genital tract by way of the blood stream, by way of the lymphatics and, secondarily, by continuity of tissue. The seminal vesicles and prostate are the primary seats of the genital tuberculous infection (though the epididymes give more pronounced symptoms) and also the foci from which the bladder and kidneys in many cases are affected.

Pathogenesis

There are two general theories concerning the pathogenesis of tuberculosis of the male genital tract.

1 That the prostate and seminal vesicles are involved primarily in the genital system and that the disease may remain localized or spread as descending genital or ascending renal tuberculosis.

2 That the prostate and seminal vesicles are involved secondarily from other urogenital organs by dissemination through the lumens or walls of hollow viscera connecting them—ascending genital or descending renal tuberculosis.

The authors believe that the disease most frequently starts in the vesicles and prostate but may occasionally start in the epididymes and that the mode of infection is primarily hematogenous.

Diagnosis

The difficulty in accurate diagnosis of the scrotal and prostatic masses has been emphasized frequently, yet the chief underlying cause is incomplete investigation.

The only method available for the examination of the prostate and seminal vesicles is palpation with the finger in the rectum. In the early stages of the disease no change may be demonstrable by this means of examination, but

in the vast majority of cases definite signs are present. Irregular firm but not stony-hard nodules in the prostate recognized by means of touch indicate extensive involvement of this organ. Likewise when the seminal vesicles are felt as pencil like bands, extending in an upward and outward direction from the upper margin of the prostate, extensive involvement of these organs is indicated.

Examination of the external genitalia is best done with the patient in a standing position facing the surgeon. Observations are made of alterations in the normal rugose appearance of the skin of the scrotum the shape of the testicles and their relative position in respect to each other. Changes in the scrotal skin are sometimes a valuable guide, as shown by a smoothing out of the rugae and a warting of the cellular tissue immediately beneath the dermis. Adhesion of the skin to the epididymis is a well-known sign, as is also a sinus discharging creamy pus. A comparison of the mobility of the two testicles is sometimes helpful. A normal organ can be moved freely within its covering particularly in the upward and downward direction. This movement is often restricted when tuberculosis of the genital organs is present. In the early stages a soft or even fluctuant mass at the site of the epididymis and involving it is present in a large percent age of cases. If untreated it will result in ulceration and formation of a chronic sinus discharging pus or it will become a hard fibrotic or calcific mass. Late in the disease the epididymis may entirely lose its identity or, if it can be palpated, will be craggy and nodular. The vas becomes thickened and has beadlike prominences.

Classification

Genital tuberculosis has the same pathological characteristics as tuberculosis elsewhere in the body and a discussion of it must take into consideration the clinicopathological type of tuberculosis, as is done by the phthisiologist in classifying pulmonary tuberculosis. The authors have classified their cases into three groups: catarrhal, 8 cases ulcerative 21 cases and fibroid, 32 cases.

Prognosis

The prognosis of genital tuberculosis does not depend entirely on the prognosis of the associated pulmonary lesion, as the authors discovered by comparing their series of cases with a comparable series of cases of pulmonary tuberculosis without genital involvement. In fact, the presence of genital tuberculosis adds considerably to the gravity of the general disease and shortens the life expectancy. At the end of a one to eleven-year period of observation, only 34 per cent of the authors' patients were alive.

Treatment

The surgical treatment recommended varies from a careful resection of the infected focus to the complete removal of the seminal tract. The immediate mortality rate of radical surgical management, the persistent draining sinuses that are frequent sequelae of such intervention and the false rationale of removing a single focus and leaving the primarily infected prostate, have placed this form of therapy in general disrepute among phthisiologists and urologists versed in the management of tuberculosis.

The beneficial effect of ultra violet therapy in extra pulmonary tuberculosis has been well known for many years. It is logical to choose a form of therapy which will lend itself to sharp localization to the desired areas that is, the prostate, the seminal vesicles and the epididymis, thus producing the maximum local effect without doing any general harm. Irradiation of the epididymis alone

has been common practice among the men who advocate this form of physical therapy for genital tuberculosis. It is the authors' belief that if radiation were given with equal intensity to the prostate and seminal vesicles, the most frequent primary seat of tuberculous infection in the genital tract, the result would be more certain and more rapid and reactivation would be less likely to occur.

The authors describe at some length their method of applying light therapy by means of the cold quartz lamp and report encouraging results in the treatment of the catarrhal and ulcerative types.—Reprinted from *Tuberculous Abstracts* (January 1940)

CORRESPONDENCE

HEALTH SERVICE, INCORPORATED

To the Editor In Boston we are soon to practice medicine in competition with a lay organization known as Health Service, Incorporated, which hires as employees the Medical and Surgical Associates. Health Service, Incorporated has already begun to solicit various groups to persuade them to allow the Medical and Surgical Associates to give them medical care. As a practitioner of medicine cannot ethically solicit patients it seems unfair for this lay organization to do so.

This is undoubtedly undermining one of the corner stones of medical ethics which has helped to keep American medicine an honored profession in the past. I believe this situation deserves a protest.

DAVID W. SHERWOOD, M.D.

66 Commonwealth Avenue,
Boston.

NOTICES

BOSTON DISPENSARY

The annual meeting and banquet of the medical staff of the Boston Dispensary will be held at the Boston City Club 14 Somerset Street, on Tuesday evening, January 23 at 6.30.

JOINT MEETING

The Boston Tuberculosis Association, the Southern Middlesex Health Association and the Trudeau Society of Boston are holding a joint meeting on Thursday January 25 at the University Club 40 Trinity Place, Boston.

The Boston Tuberculosis and Southern Middlesex Health associations will have their business meetings with election of officers at 4.30 and 5 p.m. followed by a dinner at 6 p.m. which will be attended by members of the three organizations. Dr. Edward G. Huber will speak on "Tuberculosis as a Future Public Health Problem."

At 8.15 p.m., Dr. Chevalier L. Jackson of Philadelphia will address the Trudeau Society on "The Role of Bronchoscopy in the Diagnosis and Treatment of Thoracic Disease." Discussion will be opened by Drs. Edward B. Benedict and Reeve H. Betts.

Physicians are cordially invited to attend.

MOSES J. STONE, M.D. Secretary
Trudeau Society

PETER BENT BRIGHAM HOSPITAL

A joint medical and surgical clinic at the Peter Bent Brigham Hospital will be held on Wednesday January 24 from 2 to 4 p.m. Drs. John Romano and Elliott C. Cutler will speak on "Fits." A clinicopathological confer

ence conducted by Dr Elliott C Cutler will take place from 4 to 5 p.m.

On Thursday, January 25, from 8 30 to 9 00 a.m. there will be at the Peter Bent Brigham Hospital, a combined clinic, conducted by Dr Elliott C Cutler, of the medical, surgical, orthopedic and pediatric services of the Children's Hospital and the Peter Bent Brigham Hospital.

Physicians and students are cordially invited to attend

BOSTON DOCTORS' SYMPHONY ORCHESTRA

The Boston Doctors' Symphony Orchestra will rehearse under Alexander Theide, former concert-master with the Cleveland Symphony Orchestra and the Philadelphia Symphony Orchestra, every

Thursday at 8 30 p.m., in Studio A, Station WMEX, 70 Brookline Avenue, Boston. Those interested in becoming members should communicate with Dr Julius Loman, Pelham Hall Hotel, Brookline (BEA 2430)

MASSACHUSETTS GENERAL HOSPITAL

A meeting of the Hospital Research Council will be held in the Ether Dome of the Massachusetts General Hospital, on Tuesday, January 30, at 5 00 p.m.

PROGRAM

Studies on the Peripheral Circulation with the Rein Thermostromuhr Dr R. R. Linton
Circulating Thyroglobulin in Normal Individuals and in Those with Thyroid Disease Dr J. Lerman
Antiphagocytic Property of Human Serum Dr C. Lyons

HENRY K. BEECHER, M.D., *Secretary*

SUFFOLK DISTRICT MEDICAL SOCIETY

There will be a meeting of the Suffolk District Medical Society at the Boston Medical Library, 8 Fenway, on Wednesday evening, January 31, at 8 15.

PROGRAM

Certain Features of the Water and Salt Exchange Dr James L. Gamble.
Variability of the Clinical and Hemolytic Manifestations of Leukemia in Childhood Dr Louis K. Diamond
Blood Ascorbic Acid Concentrations in Terms of Plasma, Red Cells and White Cells Dr Allan M. Butler
The Criteria for Ligation of the Patent Ductus Arteriosus in the Light of the First One and a Half Years' Experience Drs John P. Hubbard and Robert E. Gross.

MILTON H. CLIFFORD, M.D., *Secretary*

JOSEPH H. PRATT DIAGNOSTIC HOSPITAL

The following talks will be given in the auditorium of the Joseph H. Pratt Diagnostic Hospital during the week of February 4:

Monday, February 5, at 4 30 p.m. Cancer of the Stomach Dr George Pack, of the Memorial Hospital, New York City

Thursday, February 8, at 4 30 p.m. Tumors of the Bone. Dr Bradley Coley, of the Memorial Hospital, New York City. Discussion by Drs Channing C. Simmons and Howard M. Clute. Reticulum-cell Sarcoma of Bone. Dr Channing C. Simmons

Physicians are cordially invited to attend these lectures

ARLINGTON AND BELMONT MEDICAL CLUBS

A combined meeting of the Arlington and Belmont medical clubs will be held at Ring Sanatorium and Hospital, on Friday evening, January 26, at 8 15.

A report on "Mental Problems of Mid-Life: A study of one hundred cases at the Ring Sanatorium and Hospital" will be given by Drs Curtis T. Prout and Albert U. Bourcier. Discussion by Drs Ezekiel Pratt and Frank J. Fleming will follow.

MICHAEL F. NIGRO, M.D., *Secretary*,
Arlington Doctors' Club

BENJAMIN SPRITZ, M.D., *Secretary*,
Belmont Medical Club

MASSACHUSETTS PUBLIC HEALTH ASSOCIATION

In celebration of its fiftieth anniversary the Massachusetts Public Health Association is holding a dinner at the Parker House, Boston, on Saturday evening, January 27, at 7 00. Dr Charles-Edward A. Winslow, School of Medicine, Yale University, will be the guest speaker. His subject will be "A Half Century of Public Health."

Physicians are cordially invited to attend (dress optional). Tickets, at two dollars apiece, can be obtained by applying to the secretary, G. Donald Buckner, 69 Coolidge Avenue, Needham, Massachusetts.

MASSACHUSETTS PSYCHIATRIC SOCIETY

The next meeting of the Massachusetts Psychiatric Society will be held at the Boston Psychopathic Hospital on Thursday evening, January 25, at 8 00.

PROGRAM

Infectious Processes in the Causation of Mental Deficiency Dr Clemens E. Benda
Physiologic Aspects of Schizophrenic Withdrawal Drs A. Angyal, H. Freeman and R. G. Hoskins.

W. FRANKLIN WOOD, M.D., *Secretary*

NEW ENGLAND HEART ASSOCIATION

The next meeting of the New England Heart Association will be held at the Beth Israel Hospital, Monday, January 29, at 8 15 p.m.

PROGRAM

Logarithmic Recording: A standardized method for studying heart sounds. Drs Joseph E. F. Riseman and M. Rappaport.
The Mechanism and Significance of the Action of Paredrine on the Veins. Dr Arnold Iglauer.
The Degree of Latent Edema After Recovery from Congestive Failure. Dr Mark D. Altschule.
Clinical and Pharmacological Observations in Paroxysmal Ventricular Tachycardia. Dr Harry Linenthal.
The Significance of Deep S₂ in the Electrocardiogram. Drs Louis Wolff and Max J. Klainer.

Observations on the Cardiac Complications in Patients Dying in Shock. Dr Paul M Zoll.

The Effect of Nitroglycerin and Theobromine Sodium Acetate on the Electrocardiogram During Exertion in Patients with Angina Pectoris. Dr A Stone Freidberg.

The Degree of Myocardial Fibrosis as Estimated Chemically by the Collagen Content Results and Interpretations. Drs Dorothy R Gilligan and Herrman L Blumgart.

Interested physicians and medical students are invited to attend.

EDWARD F BLAND M.D. *Secretary*

NEW ENGLAND SOCIETY OF PHYSICAL MEDICINE

The next meeting of the New England Society of Physical Medicine will be held at the Hotel Kenmore, Boston, on Wednesday evening January 24. The council will meet at 6:00 there will be an informal dinner at 6:30.

Dr A. Philip Mooradian of New York City will speak on the subject, "Comparative Physics of Long Wave and Short-Wave Diathermy Generators." A question period will follow.

All members of the medical profession are cordially invited to attend.

WILLIAM D McFEE, M.D., *Secretary*

SOCIETY MEETINGS AND CONFERENCES

CALENDAR OF BOSTON DISTRICT FOR THE WEEK BEGINNING SUNDAY, JANUARY 21

SUNDAY JANUARY 21

4 p.m. What about Sulfisilamide? Dr Chester S. Keeler. Free public lecture. Harvard Medical School amphitheater of Building D.

MONDAY JANUARY 22

American Academy of Orthopaedic Surgeons. Hotel Statler Boston.
12:15-1:15 p.m. Clinicopathological conference. Dr S. Bert Wolfbach. Peter Bent Brigham Hospital amphitheater.

TUESDAY JANUARY 23

American Academy of Orthopaedic Surgeons. Hotel Statler Boston.
9-10 a.m. X-ray Clinic: Presentation of Cases. Dr A. Ertlinger. Joseph H. Pratt Diagnostic Hospital.
10 a.m.-12:30 p.m. Boston Dispensary tumor clinic.
12:15-1:15 p.m. X-ray conference. Dr Merrill C. Bowman. Peter Bent Brigham Hospital amphitheater.
6:30 p.m. Medical staff of Boston Dispensary. Boston City Club.
8:15 p.m. Boston Lying-in Hospital. Journal Club.

WEDNESDAY JANUARY 24

American Academy of Orthopaedic Surgeons. Hotel Statler Boston.
9-10 a.m. Hospital case presentation. Dr S. J. Thannhauser. Joseph H. Pratt Diagnostic Hospital.
12 p.m. Clinicopathological conference. Children's Hospital amphitheater.
2-4 p.m. Joint medical and surgical clinic. Peter Bent Brigham Hospital.
6 p.m. New England Society of Physical Medicine. Hotel Kenmore.

THURSDAY JANUARY 25

American Academy of Orthopaedic Surgeons. Hotel Statler Boston.
8:30-9:30 a.m. Combined clinic of the medical, surgical, orthopedic and pediatric services of the Children's Hospital and the Peter Bent Brigham Hospital at the Peter Bent Brigham Hospital.
9-10 a.m. Otolaryngology Clinic: Presentation of cases. Dr P. L. Metzger. Joseph H. Pratt Diagnostic Hospital.
4:30 p.m. Boston Tuberculosis Association. University Club.
6 p.m. Southern Middlesex Health Association. University Club.
8 p.m. Massachusetts Psychiatric Society. Boston Psychopathic Hospital.
8:15 p.m. Trudeau Society of Boston. University Club, 40 Trinity Place, Boston.

FRI. & JANUARY 26

9-10 a.m. Peritoneoscopy in Diagnosis of Abdominal Tumors. Dr W. E. Garrey. Joseph H. Pratt Diagnostic Hospital.
10 a.m.-12:30 p.m. Boston Dispensary tumor clinic.

5 THURSDAY JANUARY 27

9-10 a.m. Hospital case presentation. Dr S. J. Thannhauser. Joseph H. Pratt Diagnostic Hospital.
10 a.m.-12 m. Medical staff rounds of the Peter Bent Brigham Hospital. Conducted by Dr. Soets Weiss.
p.m. Massachusetts Public Health Association. Parker House, Boston.

BOOK REVIEWS

Thus We Are Men Walter Langdon-Brown 344 pp. New York Longmans, Green & Co, 1939 \$3.50

The author has collected papers from many sources and reproduced them in book form. He was formerly the professor of physic at the University of Cambridge and, for many years, physician to St. Bartholomew's Hospital. Many of these papers have appeared in medical journals. They deal with a wide variety of topics, mostly of a historical or philosophical nature. There are two short interesting biographies, one of Robert Bridges and the other of William Osler. Other distinctly medical topics deal with the background of Harvey, the plague of England and the evolution of death. All are written in a pleasant, easy style. The wide learning of the author is everywhere in evidence. He does not write in the modern popular manner, but nevertheless these essays are extremely valuable for the physician and the more informed of the lay public. The high literary standards of the English physician are upheld by this book.

The New International Clinics Original contributions, clinics and evaluated reviews of current advances in the medical arts Edited by George M Piersol Vol 3, N S 2 332 pp Philadelphia, Montreal and New York J B Lippincott Co, 1939 \$3.00

Leading off with an excellent summary of the salient facts regarding peripheral vascular disease, this volume continues with a carefully chosen group of articles too numerous to mention individually. The subjects covered are diverse, and the manner of presentation is of high caliber. Some of the articles are eminently practical, such as one concerning the surgical treatment of hemorrhoids, others, such as one discussing studies on leukemia, delve into the experimental aspects.

Sleep and Wakefulness As alternating phases in the cycle of existence Nathaniel Kleitman. 638 pp Chicago The University of Chicago Press, 1939 \$5.00

The author of this book, now associate professor of physiology at the University of Chicago, offers students a stimulating and critical account of sleep and wakefulness. The discussion is chiefly limited to the contributions which have been made since the appearance in 1912 of Pierson's book, *Le Probleme Physiologique du Sommeil*. The author's own interest and work in this field of investigation date from 1921. He has been led to evolve what he terms the evolutionary theory of sleep and wakefulness, a concept which involves the organism as a whole and is in contrast to the previously held theories, such as the neural, the humoral or the combination of both, the neural and the humoral. The book is divided as follows: Part I, "Functional Differences between Wakefulness and Sleep", Part II, "The Course of Events during the Sleep Phase of the Cycle", Part III, "Periodic Characteristics of Both Phases of the Cycle", Part IV, "Interference with the Sleep-Wakefulness Cycle", Part V, "Spontaneous Changes in the Sleep-Wakefulness Cycle", Part VI, "Means of Influencing the Sleep-Wakefulness Cycle", Part VII, "States Resembling Sleep", Part VIII, "Theories of Sleep".

There is an excellent bibliography which covers 72 pages and contains 1434 references. Author and subject indices follow.

This book is a valuable contribution to the subject, and students of biology will read it with much profit.

NUMBER 4

THROMBOPHLEBITIS AND ITS PULMONARY COMPLICATIONS*

LEWIS A. CONNER, M.D.†

NEW YORK CITY

THE presentation before this assembly of a paper bearing the above title must seem to you very much like carrying coals to Newcastle, in view of the very important contributions made to that subject by a distinguished member of your own body, Dr. John Homans. These contributions have been marked by a clarity and sanity that have set them quite apart from much of the voluminous literature that has gathered about this subject.

It seems somewhat strange that I should again at this time, be discussing the perennial topic of thrombophlebitis, for most of my experience was gained, and my writing done, over a ten year period beginning thirty five years ago. That was a time when typhoid fever was still one of the great scourges of the country, and anyone in charge of an active medical hospital service had all too many opportunities to become familiar with thrombophlebitis as it was seen in that disease. Although I have, of course, seen many cases of venous thrombosis since that time, what I have to say is based largely on my experience in studying many hundreds of cases of typhoid fever during that period. Just how far the experiences with thrombosis as a complication of typhoid fever can be carried over to other forms of thrombophlebitis is perhaps a question, but I have a strong conviction that, along with obvious differences, there are a good many resemblances between the picture of venous thrombosis as seen by the surgeons, the gynecologists and the obstetricians, and that so commonly met with as a complication of typhoid fever. It is only because of that conviction that I venture to bring this subject before you today.

First, a word must be said about terminology. I shall assume that the terms "thrombophlebitis" and "venous thrombosis" can be used interchangeably, although obviously that should not be the

case, they should have a quite different connotation, but the difficulties of making a sharp distinction between the two conditions are so great as to be almost insuperable. Many cases which seem to begin as a pure thrombosis, with no evidences of inflammation of the vein wall, later, somewhere along the course of the vein, show unmistakable signs of phlebitis and periphlebitis. Again, there may be the frank signs of phlegmasia alba dolens in one leg, with extensive signs of periphlebitis while later in the other leg the evidences of thrombosis may appear without any of the usual signs of inflammation.

Before attempting to discuss the clinical aspects of venous thrombosis, and more especially the preventive aspects, which have for us by far the greater interest, it is necessary that we have a clear understanding of the structure and mode of formation of such thrombi and so at the risk of being tedious I must review some of the more essential of the known facts.

If a typical completed thrombus, such, for example as is found in the femoral vein be examined macroscopically, it is seen to be a cylindrical plug, often many centimeters in length which has been likened to appearance to a serpent. The short proximal portion or head is of white or grayish color, and has a somewhat conical extremity, the intermediate portion or neck is of mixed whitish and red color, whereas the most distal portion or tail is a deep red and has the appearance of a postmortem clot. This red tail usually makes up much the largest part of the thrombus. It has long been firmly established that the head or white portion of the thrombus represents its primary and essential part and that the red terminal portion is secondary and, as it were, purely incidental. The structure of the white thrombus is therefore of special interest.

Without attempting a detailed description it may be said that this primary part of the thrombus is composed almost wholly of blood platelets or

*Presented at the New England Postgraduate Assembly, Cambridge, Massachusetts, October 31, 1939.

†Professor of clinical medicine, Cornell University Medical College; consulting physician, New York Hospital, New York City.

thrombocytes, which have been deposited on the vein wall by the flowing blood, and have been built up into a complicated structure resembling the intricate branching of coral, until gradually the vein lumen has become occluded.

In the interstices of this structure of platelets are to be found leukocytes and a few red cells, but fibrin, the characteristic element of blood coagulation, is almost wholly lacking. When this white thrombus has occluded the vein and blood has ceased to flow, there is then formed behind it the red, coagulated mass which makes up the tail. The platelet thrombus is firmly cemented to the vein wall by a process of agglutination, whereas the friable red thrombus has little or no such attachment.

These distinctions between the primary process of thrombosis and the secondary one of blood coagulation behind the thrombus are vital to an understanding of the subject.

This simple form of completed thrombus, however, is by no means the only one. In many cases—in most cases, perhaps—there is continued propagation of the thrombus centrally by repeated deposits of masses of agglutinated platelets, with intervening areas of red clot. When, as is usual, the proximal end of the thrombus is formed by the firmly adherent platelet thrombus, the chances of a large pulmonary embolus are small, but when in the stagnant blood between the proximal end of the thrombus and the next entering branch above a loose and fragile red clot is formed, this may extend for some distance into the blood stream above the entering branch, and be broken away and carried into the pulmonary arteries. Homans¹ believes these propagated red clots to be the source of most of the fatal pulmonary emboli.

I shall not burden you with a detailed consideration of the various causes of thrombosis. These have recently been discussed by Homans¹ with commendable clearness and conciseness. It is unquestionably true, as Aschoff said long ago, that thrombosis is "the function of a number of variables." Variations in blood flow, both general and local, changes in the composition of the blood and changes in the vein wall all doubtless play their part, although in varying degrees of importance.

With respect to the first of these sets of causes, variations in blood flow, I am strongly of the opinion that the general slowing of the blood current, as seen in many diseases of the heart, is a far less important factor in producing venous thrombosis than are the local disturbances of blood flow in the veins themselves. The beautiful experimental work of Aschoff and his associates² has shown the importance of eddies and aberrant

currents in the veins in determining the sites at which the deposition of platelets begins, and such eddies and aberrant currents, when associated with local slowing of the venous blood stream, as the result of long-continued recumbent posture, absence of muscular contraction and perhaps pressure upon the veins from any one of several causes, seem to me to constitute the important causal factors in most of the thromboses which form in the veins of the lower extremities.

The role played by changes in the composition of the blood is still obscure, in spite of the vast amount of study that has been given to such changes. Dehydration, from any of the many possible causes, is perhaps the one most likely to be significant and the one most easily understood. Of late, much stress has been laid on the importance of an increase in the tendency to coagulation among the factors predisposing to venous thrombosis, and clinical means for measuring that increased tendency have been devised³, but the significance of an increase in the coagulability of the blood as a predisposing cause can hardly be looked upon as fully established, and there seem to be such theoretical difficulties in accepting that view that I believe we should still exercise some reserve concerning it.

It would seem plausible to expect that an increase in the number of blood platelets in the circulating blood might well predispose to venous thrombosis, but no such relation between an increase in the platelets and a tendency to thrombosis has ever been found.

It is obvious that in many cases changes in the vein wall from trauma or infection must be of paramount importance among the factors leading to thrombosis. Homans⁴ has made the important suggestion that in the characteristic and severe form of phlegmasia alba dolens which complicates childbirth and infections within the pelvis, the involvement of the femoroiliac vein may result from infection along the lymphatics from the pelvis, with first a lymphangitis about the femoral vessels and only secondarily an involvement of the vein itself. However, among the large group of medical forms of thrombosis it is difficult to see how changes in the vein wall can play any thing but a very minor etiologic role.

Turning now to my experiences with venous thrombosis in typhoid fever,⁵ this complication was found to occur so frequently among the typhoid patients at the New York Hospital as to attract the attention of everyone on the medical service. It was then found that, by careful daily examination of the lower extremities of every typhoid patient throughout the course of his disease, it was possible to recognize a beginning thrombosis, often

many days before the classic symptoms of femoral thrombophlebitis appeared, and to recognize also many minor forms of thrombosis that never at any time developed the picture of phlegmasia alba dolens. It soon became quite apparent that the usual statistical figures for the complication of venous thrombosis in typhoid fever, 2 or 3 per cent. were far too low, and that the true incidence of the complication was probably not less than 10 per cent.

This daily routine examination of the legs of the typhoid patients revealed that almost invariably the thrombotic process began somewhere below the knee. Most frequently the first signs appeared deep in one or both calves with pain or soreness on stretching of the calf muscles, a small area of tenderness, with or without induration, or slight localized edematous swelling. Much less frequently the signs first appeared in the foot, with tenderness and perhaps induration either about the heel or deep in the sole. Often these signs were so equivocal that it was impossible to be sure that they indicated a thrombosis until more characteristic signs appeared either in the leg or thigh. One striking feature of the small early thromboses of the legs—a feature which seems to mark most forms of venous thrombosis—was the rarity with which the subcutaneous veins became involved. Aside from a few cases in which the long saphenous vein became affected, the process was confined almost exclusively to the deep veins.

The progress of the clinical signs of most of these thromboses was upward, the first signs appearing in the calf or foot, later with the signs indicating the involvement of the popliteal vein and finally with the signs of a full-blown phlegmasia alba dolens, affecting the femoral vein alone or the femoral and iliac veins. Not all cases, however, showed this tendency toward upward extension of the thrombosis to the femoral vein. In a considerable number the process seemed to confine itself entirely to the veins in the lower leg. Only rarely did signs of femoral thrombophlebitis appear as the first evidence of thrombosis. Another point of interest relates to the occurrence of extensive periphlebitic inflammation. When this was found it seemed always to be the final phase of the process of thrombosis, and one got the impression (it never was more than an impression) that pronounced periphlebitic inflammation and induration occurred only after the vein had become completely occluded.

The time interval between the first signs of thrombosis in the calf or foot and the frank signs of femoral thrombophlebitis varied greatly, it might be only two or three days but it might, on

the other hand, be as long as three or four weeks.

Marked edematous swelling of the thigh and leg was by no means a very common symptom, even when the signs indicated the involvement of the femoral vein, and when present such swelling appeared usually only in connection with pronounced signs of phlebitis and periphlebitis.

In studying the symptom of fever in the cases of thrombophlebitis complicating typhoid fever, there were certain obvious difficulties. Often the fever of the disease itself had not altogether subsided before the signs of thrombosis appeared, and there was besides the possibility that any existing fever might be caused either by a relapse or by some other complication. However, it was found after the study of a great many temperature charts that the fever curve in uncomplicated typhoid fever had a very characteristic and uniform type and even though it varied widely in its duration and height the same was true also for the relapses. No matter whether they were mild or severe they showed the same periods of gradual ascent, of continuous elevation and of gradual decline.

When the temperature charts of the cases complicated by venous thrombosis were studied it was found that some post typhoid febrile movement was present in almost all the cases. In a majority of the cases the temperature rose with the appearance of the signs of thrombophlebitis in a large vein. Often however the fever began several days or even longer before any of the usual signs of thrombosis had appeared. The height of the fever, as well as its duration and its time of appearance, showed every possible variation. In a number of the cases there was fever for some days preceding the appearance of the signs of thrombosis but none afterward. In others the temperature rose only after the thrombosis had been manifest for several days. In a good many of the cases, after the period of typhoid defervescence had become nearly or quite complete, the temperature would rise again and then run a long and irregular course, in the midst of which at some time, appeared the signs of thrombosis.

It is my hope that the above mentioned facts concerning the clinical picture of venous thrombosis as it appears in typhoid fever may to some extent at least, be applicable to venous thrombosis as it is seen by surgeons and obstetricians.

I come now to two bizarre symptoms which in the study of 1540 cases of typhoid fever were found to be so frequently associated with the signs of venous thrombosis that one could not but feel that the relation must be something more than a purely fortuitous one.* They are mentioned here on the chance that rarely perhaps, they may be encountered in other forms of thrombophlebitis. I

refer to the symptoms known as "post-typhoid chills" and "tender toes"

One of the less common but well-recognized complications or sequels of typhoid fever was the obscure, multiple chills which occasionally marked the period of convalescence. Such abrupt rises of temperature and rigors might occur almost daily for two or three weeks without obvious cause, either at the time or afterward. They were usually referred to as manifestations of "post-typhoid sepsis," although there were no other evidences of sepsis and although their course was invariably benign. In the above series of typhoid-fever cases such obscure, late, multiple chills occurred in 20 patients. In 16 of these there were well-marked signs of thrombophlebitis, and in every one of the 4 cases in which no signs of thrombophlebitis were observed, there were pulmonary symptoms strongly suggestive of pulmonary embolism. These recurring chills bore no constant time relation to the appearance of the symptoms of venous thrombosis. Very often the chills occurred some days or even two or three weeks before the signs of thrombosis in the legs appeared. At other times the chills occurred simultaneously with the signs of thrombosis. At times the chills synchronized with the signs of pulmonary embolism, but frequently there was no such recognizable relation. Just what the significance is of these multiple chills I do not know, but that they have some relation to the process of venous thrombosis is, I think, beyond question.

The obscure condition of painful and exquisitely tender toes has long been known as an occasional complication of typhoid fever, and appears late in the disease or during convalescence. It was commonly regarded as a neuritis of the plantar nerves, although in many cases the transient character of the symptoms made it seem unlikely that an actual neuritis existed.

In the series referred to, this complication occurred in 22 cases. In 12 (55 per cent) of these there was also the complication of thrombophlebitis of the legs. Of the 10 cases of tender toes in which venous thrombosis was not recognized, there were 7 which at the time of the tender toes showed an irregular and unaccountable post-typhoid febrile movement, and in 1 of the remaining 3 cases there were the symptoms of pulmonary embolism. These facts are at least very suggestive of some connection between thrombosis involving the legs and the mysterious symptoms of tender toes. It is unlikely that thrombosis and inflammation of the small veins of the foot should themselves produce the symptoms, but it seems reasonable to suppose that a thrombosis

of one or more veins about the heel and the subsequent periphlebitic inflammation might in some cases be sufficient to irritate, or even to cause inflammation of, the plantar nerves which lie in such close contact with the arteries and their venae comites.

These features of the clinical course of venous thrombosis as seen in typhoid fever have been discussed at length only in the hope that they may throw some light on those forms of thrombosis that are of such importance at the present time, for typhoid fever is now so rare that its complications hold little interest for us.

The postoperative forms of thrombosis have always been regarded as being especially characterized by their tendency to run a latent and silent course. Whether that belief is justified, I do not know, but it seems to me possible that the careful daily examination of the lower extremities of postoperative patients, from the time of their operation onward, might occasionally reveal evidences of early thrombosis in the calves or feet some days before a femoral thrombosis had declared itself by the occurrence of a fatal pulmonary embolism. I need hardly add that such examinations of the legs, if attempted, should be carried out with the utmost gentleness and caution.

In view of the various other symptoms which were found so often associated with venous thrombosis in typhoid fever, it seems possible too that the presence of a febrile movement for which there is no satisfactory explanation might, at times, furnish the correct clue. It is hardly necessary to say that any sudden pulmonary or pleural symptoms, however soon they may appear after operation or childbirth, should be looked upon with the utmost suspicion. Whether the two strange symptoms of recurrent chills and tender toes, which seemed to bear some relation to venous thrombosis in the typhoid patients, ever have their counterparts in the thrombophlebitis cases of the present day, I should be greatly interested to know.

Thus far nothing has been said concerning what is after all the most important group of symptoms associated with thrombophlebitis—those related to the lungs. An analysis of the large series of typhoid cases referred to showed that in 88 cases there had been pulmonary or pleural complications (exclusive of bronchitis), which in 25 cases were almost certainly not of an embolic nature. Of the remaining 63 cases it was believed that most if not all were those of pulmonary embolism, although in some of these cases no other evidence of venous thrombosis had been recognized.

The custom of making a sharp distinction between the type of massive embolism which usu-

ally results fatally and the far commoner type of minor embolism with infarction is, I think, fully justified. Among our typhoid patients such fatal attacks occurred only three times, and in each case only late in the course of the venous thrombosis and only after there had been earlier mild attacks. On the other hand, the small embolic attacks were vastly commoner, were frequently multiple and occurred much earlier in the course of the thrombosis. In two thirds of the cases these embolic attacks occurred before any local signs of thrombophlebitis had appeared, the interval between the two groups of symptoms being anywhere between two or three days and two weeks or more. I⁶ have supposed that these early and small emboli were derived from the freshly forming mural thrombus before the vein is occluded and while the blood is still flowing in it. That is the time when the thrombosis usually gives no local symptoms, and is the time also when one would naturally expect small clumps of agglutinated platelets to be washed away into the venous blood stream. Indeed, it is hard to understand how a gradually forming thrombus can avoid giving off such small and early emboli. These early embolic attacks, occurring before the local signs of thrombophlebitis, were described by Vaquez⁷ almost half a century ago.

The late, massive emboli I have always believed were the result of the dislodgment of a large portion of the completed thrombus, which for some reason had not become firmly fixed to the vein wall. It may well be, however, as Homans¹ thinks, that many such emboli are due to a loosely attached red clot which has formed in advance of the platelet thrombus. Certainly when there are distinct evidences of phlebitis and periphlebitis the risk of detachment of the thrombosis seems very remote. Barker and Counseller⁸ state that in a series of 116 fatal cases of embolism from post-operative thrombophlebitis the latter was recognized before death in only 5 cases. In 4 of these cases autopsy revealed that the thrombus was intact in the leg in which it had been recognized during life and that the fatal embolus had come from an unrecognized thrombus in the other leg.

It is unnecessary to discuss at length the symptoms of pulmonary embolism and infarction. Their severity is, of course, determined chiefly by the size of the infarct.

Pleural pain is usually the first, and is much the most constant, of all the symptoms. In many of the cases its location along the margin of the ribs or at the top of the shoulder suggests that the infarct is at the diaphragmatic surface of the lung. A good many of the emboli are so tiny and lodge so close to the surface of the lung that the resulting

infarct is too small to be detected by physical signs or even by an x-ray film. In such cases the only signs may be those of a very transient dry pleurisy.

In the case of larger infarcts there may be the signs of a circumscribed area of consolidation or of an extensive fibrinous pleurisy.

Bloody sputum, the presence of which is so often looked upon as essential to the diagnosis of pulmonary infarction, is by no means a constant symptom. It occurred in less than half our typhoid cases of embolism. Even when it is present it may not appear until three or four days after the onset of the symptoms. In only a small percentage of the cases is the onset of the attack marked by a chill, and the elevation of the temperature is often less marked and less protracted than one might reasonably expect from the severity of the other symptoms.

We come now to the all important questions of prevention and treatment, and here I speak with much less confidence than I did when discussing the clinical picture of the disease.

In the case of the typhoid patients we were dealing with severely ill and prostrated people who often had lain for several weeks flat on their backs, with the legs fully extended and with almost complete lack of the important aid to venous circulation that is furnished by muscular contraction. In many of the patients also there must have been a state of severe dehydration.

The fact that thrombosis almost always began in the veins of the calf or foot suggested that there might be some special interference with the venous return just above these points, and led me to wonder if in these outstretched legs the tension of the deep popliteal fascia might not offer some additional impediment to venous return by compressing the popliteal vein which lies directly beneath it. It must be admitted that the simple procedure of elevating the foot of the bed as a prophylactic measure in all the typhoid cases did not seem to occur to anyone. The patients were, however, encouraged to change their position in bed, to move their limbs freely and to keep the knees partly flexed.

The importance of the lack of muscular contraction in favoring thrombosis seemed to me so great that once when one of the interns became ill of typhoid fever I was led to propose to him that he might perhaps lessen the chances of thrombosis by light exercise of his arms and legs at frequent intervals every day. He was eager to follow my suggestion and as he was not too ill to do so, these daily exercises of his arms and legs were continued through most of his illness. Unfortunately he was a conscientious lad and the exercises were carried out only too faithfully and energetically.

To my great embarrassment he developed an extensive thrombophlebitis, first in one arm, then in the other and finally in both legs. It was, I think, the most extensive involvement of the veins that I have ever seen. Just what conclusion should be drawn from this experience I have never quite known, but at all events it effectually dampened my enthusiasm for muscular exercise as a preventive measure.

In the management of postoperative patients there is the growing conviction that the time to employ preventive measures against thrombosis is the period immediately after the operation rather than a week or two later. That conviction is, I think, fully justified, for in many cases, at least, thrombosis is a gradual process which has its beginning much earlier than might be supposed. Elevation of the foot of the bed to hasten venous return from the legs, the avoidance, so far as possible, of everything that increases intra-abdominal pressure, the stimulation of active diaphragmatic breathing movements and the replacement of losses of body fluids are all measures which are reasonable and practicable and which deserve to be employed. Whether an increased tendency to blood coagulation predisposes to thrombosis and

whether, if that be the case, such a tendency can be effectively controlled, as Bancroft and his associates³ believe, by diet or drugs I do not know. Certainly much the most promising of the newer measures to prevent thrombosis is the use of the purified preparations of heparin, not because it is an effective anticoagulant, but because it has been shown in a very striking way by Best and his colleagues⁹ to be capable in experimental animals of preventing the formation of the platelet thrombi. What the value of this method, and what the limitations of its usefulness may prove to be as a routine measure in postoperative cases, can only be determined by further experience.

EXSTROPHY OF THE BLADDER AND EPISPADIAS*

WILLIAM E. LADD, M.D.,† AND THOMAS H. LANMAN, M.D.‡

BOSTON

THREE years ago we¹ presented before this society the results of our operative treatment of exstrophy of the bladder. The data were based on a study of 15 patients, and we emphasized the following points:

A three-stage operation.

The transplantation of the right ureter first, and the left two to four weeks later.

The transperitoneal approach for the ureterosigmoidostomies, leaving no catheter or guides, but having the proximal end of the ureter opened widely by a longitudinal split.

No drainage of the peritoneal cavity.

Removal of the bladder as soon as is practicable after the ureteral transplants.

The operation to be performed, preferably, between three and five years.

In the last three years there have been 7 addition-

al cases, making a total of 44 ureterosigmoidostomies in 22 patients with exstrophy of the bladder which we have performed without mortality. This is good evidence that the guiding principles set forth in our previous paper are sound. Not only has there been no mortality, but the functional results have been satisfactory in the cases observed to date. We have been greatly pleased by the later follow-up study of some of our earlier cases. Intravenous pyelograms taken six or seven years after the original transplantations have shown little if any evidence of dilatation of the ureters or kidney pelves in a satisfactory number of cases. It is also interesting to note that some of the cases have shown rather more dilatation of the ureters and kidney pelves during the first two years after the transplantation than they have subsequently. It is possible that the dilatation shown during the first six to eighteen months after operation may be explained on the basis of a physiologic readjustment to the transplantation.

Our previous paper and most of the other recent papers in the literature on exstrophy of the bladder have concentrated on the diversion of the

§Assistant professor of surgery, Harvard Medical School; visiting surgeon, Children's Hospital, Boston.

urinary flow into the bowel. Comparatively little attention has been paid to the remaining factors in the problem. These factors are removal of the pouting exstrophied bladder, which is unsightly and uncomfortable, cure of the ventral hernia, which is always present, plastic reconstruction of the urethra with possible restoration of sexual function, and cosmetic improvement, which is important psychologically, particularly in the male.

One of us (W.E.L.) has devised the following method which satisfactorily solves the above parts

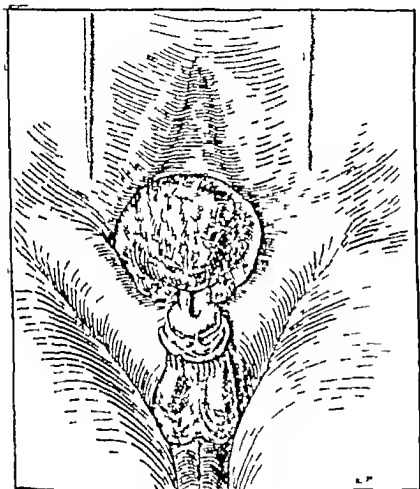

FIGURE 1

Shows exstrophy of the bladder subsequent to ureteral transplants but before any operative procedure for the epispadias

of the problem. No particular claim for originality in principles is made for this operation, but rather it is an adaptation and combination of the principles used by others into a single operation which yields gratifying results. The use of the foreskin for the outer skin layer covering the newly made urethra is based on the practice of Ombredanne in the treatment of hypospadias, and is somewhat similar to that of Luhmann² in the treatment of epispadias, but the details of our technique are quite different from either of these.

At a suitable time after the ureters have been transplanted, usually three to five weeks, the cystectomy and repair of the epispadias and ventral hernia are undertaken. It should be remembered, however, that this third step requires a rather long anesthesia and is accompanied by an appreciable,

though seldom dangerous, amount of hemorrhage. It should never be done, therefore, unless the patient has fully recuperated from the previous ureterosigmoidostomies. In certain cases the child may well be sent home for a period of weeks or months to recuperate. This is often time well spent, for the child can lead a much more normal and active life than he could before the ureteral

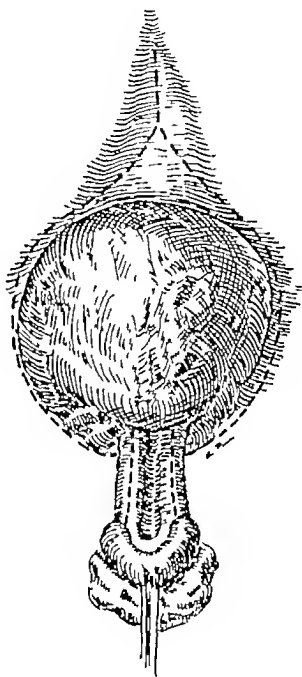

FIGURE 2

Shows incision for the operation

transplants. Also, he usually acquires urinary control during this period, which makes the convalescence from the third operation much more comfortable.

OPERATION

Under Avertin, nitrous oxide and oxygen, and ether anesthesia, the patient is prepared and draped. The exstrophied bladder is cleaned with soap and water and then with alcohol. The surrounding skin of the abdomen, and of the genitalia in boys, is prepared with one-third strength iodine solution.

Figure 1 shows the appearance of the male patient before operation. Note the urethral groove, the prepuce, which is hooded on the under side of the glans penis, and the wide separation of the two recti muscles.

Figure 2 shows the line of incision for the cystectomy. It should come a little to the outer side of the junction of the mucous membrane and the skin. At the upper end it should be carried still farther away from the mucous mem-

moving the bladder mucous membrane and folding over the flap of rectus fascia to cure the ventral hernia, and closing the subcutaneous fascia and skin in the midline. In boys, the plastic repair of the epispadias is now undertaken.

Figure 4 shows the bladder mucous membrane still attached at the base in the region of the verumontanum. The dotted line shows the incisions that are made to construct an oblong flap of mucous membrane with its hinge at the base

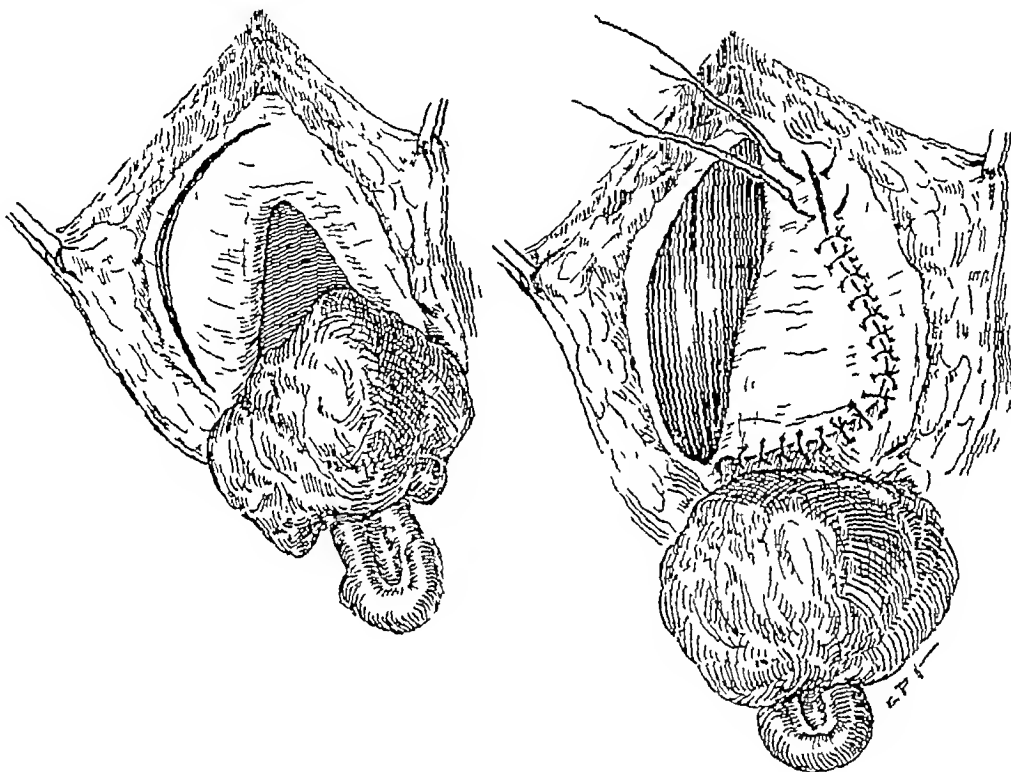

FIGURE 3

Shows the bladder freed and turned down, and the method of closing the ventral hernia with the fascial flap

brane of the bladder until the two lateral incisions meet at a point above the site of the navel.

Figure 3 shows the bladder almost entirely resected. It also shows how a large, generous flap of fascia from the right rectus muscle is made and then turned across to the opposite side to close the triangular defect in the anterior abdominal wall. Particular caution must be used in dissecting the bladder mucous membrane at the upper third, for it is here that it is very easy to enter the peritoneum. Should this misstep be made, the peritoneum should be closed at once with plain catgut. We have had no ill effects in the cases where the peritoneum has been accidentally opened. This method of removal of the bladder mucous membrane and repair of the abdominal wall defect is the same in both sexes. In girls the operation is completed by entirely re-

moving the bladder mucous membrane and folding over the flap of rectus fascia to cure the ventral hernia, and closing the subcutaneous fascia and skin in the midline. In boys, the plastic repair of the epispadias is now undertaken.

Figure 5 shows the various steps in making the mucous-membrane roof to the urethra and the method of covering it with the split prepuce. Figure 5₁ shows the mucous-membrane flap being turned forward, and Figure 5₂ its suture to the incision previously made on either side of the urethral groove. Figure 5₃ shows the prepuce being split by blunt dissection through the incision previously made around and beneath the glans. Figure 5₄ shows the prepuce split

and turned outward with the raw surface presenting, and the roughly triangular incision through which the glans is drawn. Figure 5a shows the glans after it has been pulled through the preputial flap, *ACBC* and how the flap is

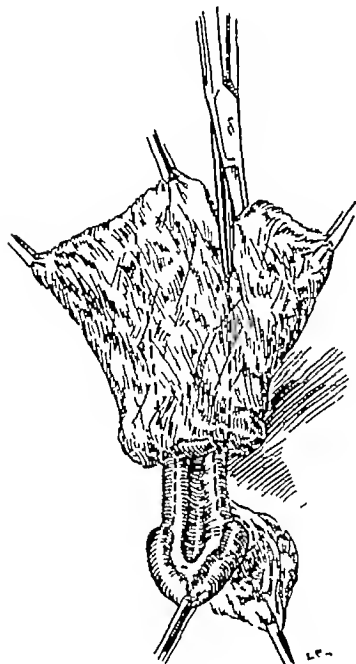

FIGURE 4

Shows the flap of bladder being cut to form the roof of the new urethra

utilized to cover the roof of the urethra. Point *A* of the flap is sutured to the bottom of the incision, closing the anterior abdominal wall. This point is at the base of the shaft of the penis. Interrupted sutures are then placed on either side running up to points *C* in Figure 5b. Thus firmly anchors the preputial flap on the raw surface of the previously made urethral tunnel. Figure 5c shows the last step, which consists in suturing the hole made in the preputial flap to the cut surface of the incision about the corona, and to the distal end of the mucous membrane flap which forms the roof of the urethra. This last step can be better visualized by saying that it is very similar to the row of sutures used in performing an ordinary circumcision. Figure 6 shows the operation completed.

On completion of the operation, it will be seen that there is some redundant tissue from the preputial flap. Its appearance has been described as dog-eared. It is better to postpone further plastic work intended to reduce the tissue for a number of months or years, as it tends to disappear with time.

When properly done, the operation has relatively little chance of failure. The chief danger,

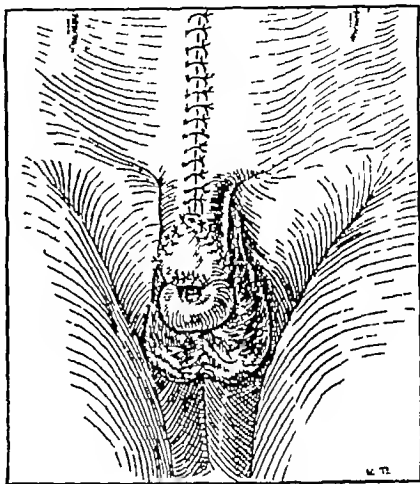

FIGURE 6.

Shows the completed operation

of course, is that of infection, but this can be minimized by proper technic. The passage of urine is obviously not a factor.

This type of operation results in a very much stronger abdominal wall, and in correcting the epispadias it creates a passage, which should remain patent, from the ejaculatory ducts to the end of the penis. As to how successful the function will be, of course, cannot now be answered. It is our intention to follow these cases for a number of years, to do further plastic procedures if necessary as the size of the organ grows, and to correct, if necessary the redundancy of the preputial flap, though this redundancy is much less noticeable a few months after operation. Of particular interest to us will be a trial, as the patient approaches puberty, of the various preparations of sex hormones which apparently are effective in increasing the size of the organ.

While the functional result must remain in doubt, we believe that this operation is an impor

tant advance over our former technic in that it gives a satisfactory cure of the ventral hernia, a more comfortable pubic area, a possible restoration of sexual function and an improved cosmetic

44 ureterosigmoidostomies justify their continuation
We present a better method of closing the defect in the abdominal wall in both sexes and also

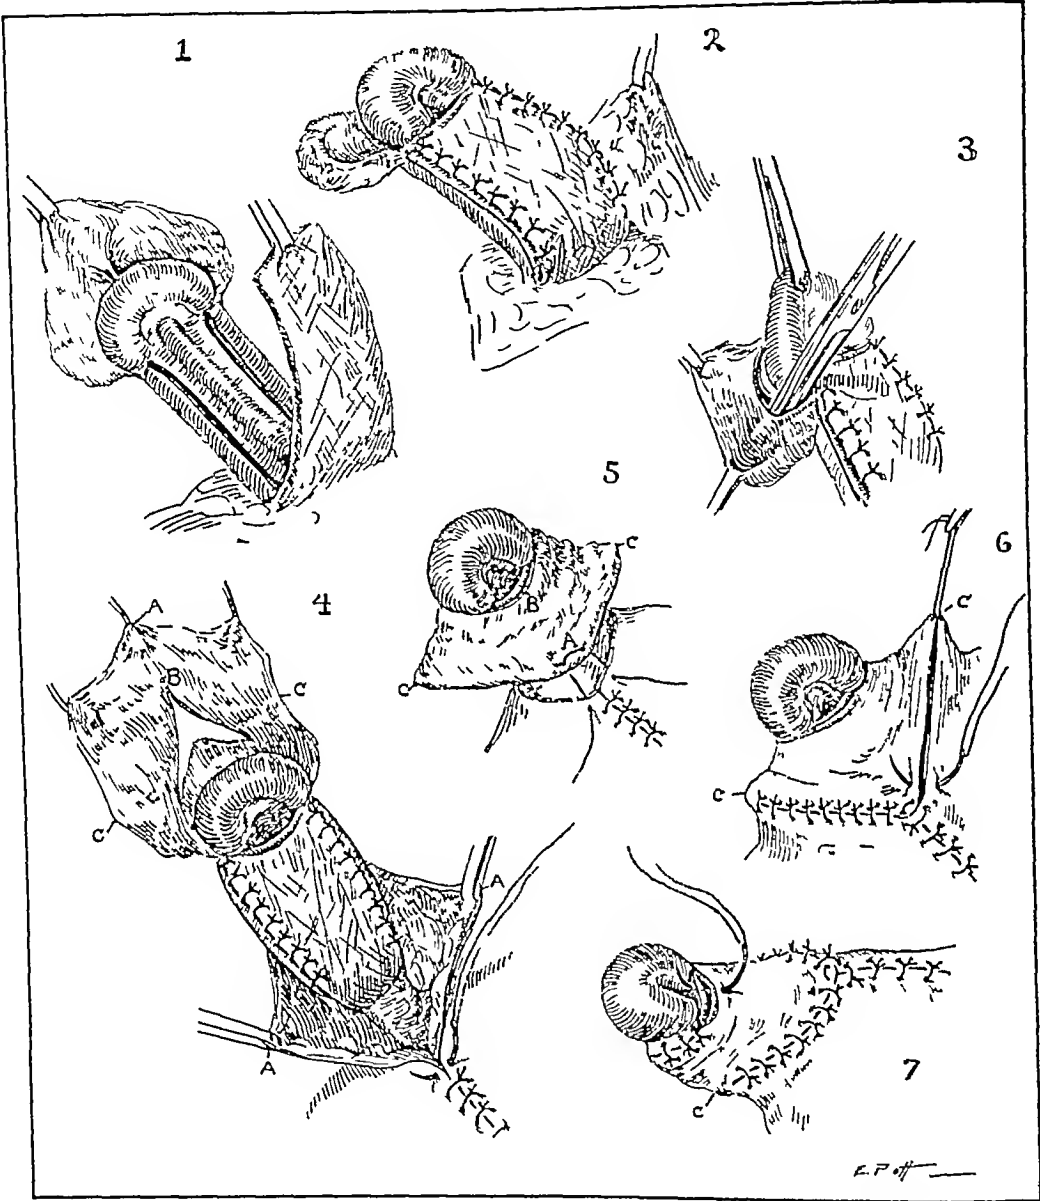

FIGURE 5

appearance with a lessening of the bad psychological effects of the malformation

SUMMARY

Seven additional cases of exstrophy of the bladder are presented. The methods previously advocated for the transplantation of the ureters have proved their worth, and the functional results in

a method of correcting the epispadias. We believe that these methods are improvements in the treatment of this distressing congenital anomaly.

TUBERCULOSIS OF THE PANCREAS

Report of a Case

RUFUS R. LITTLE, M.D.*

WALLUM LAKE, RHODE ISLAND

TUBERCULOSIS of the pancreas is an exceedingly rare condition, hence the following case report should prove to be of interest

CASE REPORT

A white Portuguese woman, 60 years of age, entered the Rhode Island State Sanatorium with the chief complaint of cough and expectoration of 5 months duration. The family history and previous medical history were irrelevant. The patient stated that about 4 years prior to admission she began to have frequent headaches pain in the left arm and epigastric distress. She soon began to lose weight, became easily fatigued and complained of general malaise. It was known that the patient had had diabetes mellitus for an indefinite time, and she was first given insulin about 1 year previous to admission. Five months previous to admission she began to have severe cough and expectoration, dyspnea, night sweats and pain in the left chest anteriorly. An x-ray film of the chest was taken and the patient sent to the sanatorium with a diagnosis of far-advanced pulmonary tuberculosis complicated by diabetes mellitus. During her stay her temperature was of the septic type, with daily afternoon elevations to 101 or 102 F with a maximum elevation to 104 F 2 days prior to death. Cough and expectoration were pronounced but the most marked clinical symptom was constant, severe epigastric pain.

The diabetes was exceedingly difficult to control. On admission the blood sugar was 222 mg per 100 cc. and the urine contained 1.25 per cent sugar. Under insulin therapy over a period of 3 weeks the urine finally became sugar-free except for an occasional slight trace. The blood sugar promptly dropped to 60 mg per 100 cc. The insulin dosage was then decreased slightly the diet remaining the same, and it was thought that the diabetes was controlled as the urine contained at most a very slight trace of sugar. However within a few days large amounts of sugar appeared in the urine and the blood sugar was found to be 434 mg. per 100 cc. Thereafter almost daily changes in insulin dosage were required to maintain the urine sugar-free and the blood sugar near normal limits.

The patient's course was steadily downhill. The sputum was constantly positive for tubercle bacilli. Ascites developed and required paracentesis, 1800 cc. of slightly opaque, serous fluid being removed. This fluid was found to contain a few pus cells, a few large mononuclear cells but no tubercle bacilli or other organisms. The patient died approximately 15 weeks after admission.

Autopsy Caseous and proliferative tuberculosis with bilateral cavitation was found in the lungs, there being involvement of all lobes. No tuberculous involvement of any other organ except the pancreas was noted. The pathologist's description of the pancreas before removal from the abdominal cavity was as follows:

In the region of the duodenum there is massive fibrosis tying down the lower border of the stomach,

Resident physician, State Sanatorium, W. Hum Lake, Rhode Island.

the pancreas duodenum and upper portion of the omentum as a mass, with stellate radiation of scar tissue centering at the duodenal curvature. Dissection of the above area discloses the head of the pancreas reduced to a mass of apparently normal pancreatic tissue about 5 cm. in greatest width and 3 cm. in thickness. The remainder of the pancreas is for the most part replaced by firm fibrous tissue containing at the splenic end a smooth walled cyst 2 cm. in diameter filled with creamy purulent fluid in which can be demonstrated acid-fast organisms by direct smear. The pancreatic duct is patent. The bile duct is not involved. The pancreatolienal nodes appear as a chain of fairly firm, normal appearing lymphoid nodules, the largest 9 mm. in the long axis.

The microscopic description of sections from the pancreas was as follows:

One section from the head of the pancreas shows extensive fibrosis of the interlobar septums and peripancreatic tissue, with the parenchyma reduced to isolated lobules and alveoli which however appear active and essentially normal. A section from the tail of the pancreas shows almost complete replacement by hyaline connective tissue in which are noted occasional identifiable islands of Langerhans and alveoli. One border of the section and a small cavity within the mass are lined with a caseous, necrotic layer beneath which appears an intense endothelial infiltration in epithelioid arrangement. Occasional microscopic tubercles contain typically tuberculous giant cells, and a direct smear from the contents of the cavity shows numerous acid-fast bacilli.

The diagnosis was tuberculosis of the pancreas, with abscess formation.

That tuberculosis of the pancreas is of rare occurrence is attested by the fact that only three articles on this subject could be found in the American literature, the most recent¹ of these being published in 1924. A few more articles were found in the foreign literature, but here too the subject has been given little attention and very few cases have been reported.

The incidence of tuberculous infection of the pancreas as determined by autopsy reports of various authors is uniformly low. Scattered military tubercles of the gland are not uncommon in association with generalized military tuberculosis, but large tuberculous lesions of the pancreas are exceedingly rare. Textbooks of medicine and pathology give practically no information on the subject, merely stating that tuberculosis of the pancreas is of rare occurrence. White² in 142 autopsies on tuberculous subjects, including military cases, found the pancreas involved in only 1

case In 683 autopsies on tuberculous subjects in the Veterans' Administration hospitals no tuberculous involvement of the pancreas was found.³ Here at Wallum Lake tuberculous infection of the pancreas was found in 1 of 10 cases of military tuberculosis. The present case is the only one in which a large tuberculous lesion of the pancreas was found, and the only case not of the military type having involvement of the gland.

That the pancreas possesses a relative immunity to tuberculosis has long been recognized. The gland was cited as an illustration of local immunity to tuberculosis as early as the middle of the eighteenth century. This fact is important in view of the location of the pancreas in the abdomen. The gland is situated in an area richly supplied with lymphatic ducts and there are always lymph nodes in the vicinity, all intercommunicating with the lymphatic vessels of the spleen, duodenum and mesentery. Tuberculous involvement of the lymph nodes around the pancreas is not uncommon, and has been erroneously reported as tuberculosis of the pancreas. The pancreas communicates directly with the intestinal tract by the pancreatic duct, affording connection with an area very frequently bearing tubercle bacilli, as evidenced by the high incidence of intestinal tuberculosis. Military tuberculosis of the pancreas is undoubtedly of hematogenous origin. Carnot⁴ found tuberculosis of the splenic end of the pancreas in contact with a tuberculous kidney. Thus there are four avenues of infection by the lymphatics, by the pancreatic duct, by the blood stream and by direct extension from neighboring organs.

Why the pancreas should exhibit a marked degree of immunity to the tubercle bacillus has been the source of much experimentation and of many theories. Carnot⁴ demonstrated the extreme difficulty of reproducing clear-cut tuberculous lesions in the pancreas. Other investigators have published similar results, all indicating that no matter what the source of inoculation, true tubercles almost never occur in the pancreas. Carnot showed that tubercle bacilli rapidly lose their virulence following experimental infection of the pancreas, so that inoculation of a guinea pig with material from the gland one week after infection produces only a localized tubercle, with no extension at the end of a month and a half. With a longer interval before inoculating the guinea pig from the infected gland it was found that the virulence of the bacilli had diminished to such an extent that they rapidly disappeared from the tissues.

Interesting experiments were performed by

Porter⁵ in 1917 in an attempt to explain the relative resistance of various tissues to the tubercle bacillus. Attributing the highly resistant qualities of the tubercle bacillus to its fatty envelope, Porter reasoned that if this envelope could be first dealt with the bacillus itself might prove vulnerable to the protective mechanism of the tissues. The lipase content of extracts of various tissues was determined. Then the bactericidal action of these extracts on several strains of tubercle bacilli was tested. The least powerful was lung extract, which contained the smallest amount of lipase, the most powerful was pancreatic extract, which contained the greatest lipase content. Porter therefore suggested that the bactericidal action was chiefly the result of the lipolytic activity of the tissue on the bacilli. This experimental work was generally accepted by most investigators, and has been quoted in most textbooks on tuberculosis.

In June, 1938, Hirschberg and Arnold⁶ reported results of experiments performed by them in order to determine the nature of the relative immunity to tuberculosis exhibited by certain tissues. The effect on cultures of tubercle bacilli of tissue juices having no lipolytic activity was tested. The degree of inhibition exerted by the various tissue juices had a direct relation to the resistance of the organs to tuberculosis, as evidenced by the incidence of infection of these organs. Pancreatin, pancreatic digest and insulin were also tested, and were found to have no effect on the tubercle bacillus. It was concluded that the nature of the inhibitory element is not known and may be considered, at least for the moment, to be nonspecific.

The case reported herein is unique in that it is characterized by a disturbance of the function of the pancreas. In 1899 Loheac⁷ wrote a thesis on tuberculosis of the pancreas in which he described detailed symptomatology. He is the only author who has recognized and reported symptoms of pancreatic insufficiency resulting from tuberculous disease of the gland. Joslin⁸ states that a small remnant of healthy pancreas will suffice to prevent diabetes, and extirpation experiments on animals have proved that diabetes will be averted if one tenth of the gland is left. Hence, the number of islands of Langerhans remaining determines the efficiency of the gland. In the case reported here the pathologist noted almost complete replacement of the tail of the pancreas by hyaline connective tissue and the large tuberculous abscess. Since the islands are normally twice as frequent in the tail as in the head, it is logical to assume that the tuberculous lesion of the pancreas was instrumental in producing the diabetes mellitus.

As spontaneous drainage from the tuberculous abscess in such a location would necessarily be by way of the pancreatic duct and would be slow and difficult, one may further assume that drainage was intermittent, with consequent variations in the size of the abscess depending on the amount of purulent material retained. It is possible that this intermittent drainage may have played a part in the marked fluctuation of the diabetic state.

The diagnosis of tuberculosis of the pancreas can, of course, be made with certainty only at the autopsy table. However, its occurrence should be borne in mind and occasionally the diagnosis may be made with a fair degree of certainty in the living patient. The one clinical symptom common to all reported cases of tuberculosis of the pancreas is persistent and distressing epigastric pain. We know that the most prominent symptom of acute pancreatitis is excruciating epigastric pain. Therefore, persistent and constant epigastric pain in a tuberculous patient should strongly suggest tuberculosis of the pancreas. If diabetes is also present the diagnosis is more probable.

That diabetes mellitus unfavorably influences the prognosis of pulmonary tuberculosis has long

been recognized, and it is not within the scope of this paper to discuss this subject.

SUMMARY

A case of tuberculosis of the pancreas is reported.

The presence of this rare condition is suggested by persistent epigastric pain in a tuberculous diabetic patient.

The exact nature of the immunity to infection by the tubercle bacillus exhibited by the pancreas has not as yet been determined, and its discovery may offer a means of producing a general immunity to the tubercle bacillus.

PENTOTHAL THE ANESTHETIC AGENT OF CHOICE FOR THE REDUCTION OF SIMPLE FRACTURES

PHILLIP S. MARCUS, M.D.*

BOSTON

IN RECENT years many publications have discussed the use of Pentothal, but no paper has yet appeared which considers the use of the drug for the reduction of simple fractures in ambulatory patients. During the last two years I have had the opportunity to administer and direct the use of Pentothal in the Out Patient Fracture Service of the Boston City Hospital and the advantages it possesses where hospitalization is not necessary or desired have made it the anesthetic agent of choice.

The ideal anesthetic agent for use in the reduction of simple fractures in ambulatory patients should fulfill the following requirements: it should provide sufficient muscular relaxation for proper manipulation and reduction, it should be of sufficient duration for manipulation and application of maintenance apparatus, it should possess a short induction and short emergence time, it should be easily administered without expensive

or elaborate equipment, it should have a wide margin of safety, it should present no contra indications, and there should be specific therapy for its administration in excess.

In the following discussion the average patient coming to the outpatient clinic or office will be considered. In such cases hospitalization is not desired. Various anesthetic agents are available, and these will be considered in order to determine which most closely approaches the ideal as described above.

ANESTHETIC AGENTS

Local Anesthesia

Local anesthesia for the reduction of simple fractures of small bones is possible, desirable and often employed. However, in dealing with large bones and with fractures requiring a considerable degree of manipulation, sufficient muscular relaxation and anesthesia are often very difficult if not

*Resident anesthesiologist, Boston City Hospital.

impossible to obtain. The induction time is often long, but the emergence time is short. This type of anesthesia is well suited for certain ambulatory cases. It has a wide margin of safety, and the only contraindications are hypersensitivity or local damage. A maximum of skill and experience are required in order to secure even fair results with local infiltration. Reactions and overdosage are combated by artificial respiration and respiratory and cardiac stimulants.

Nitrous Oxide

Nitrous oxide is a widely used and much abused anesthetic. It is the weakest gaseous anesthetic and is employed with varying concentrations of oxygen. Without medication it will in a majority of cases produce sufficient relaxation for reduction only if pushed to clinical or subclinical cyanosis. This anoxemia continued for a sufficient length of time for reduction and maintenance may produce damage to the brain that is definitely more serious than the original injury. There is marked excitement during induction and actual bodily restraint is often necessary. Furthermore, the following accidents and complications during induction must be considered: violent respiratory spasm with alarming degrees of cyanosis, vomiting with the inhalation of vomitus, sudden death due to ventricular fibrillation, and further physical trauma.

The duration of anesthesia may be insufficient, particularly if the reduction slips during the application of plaster or traction apparatus. The emergence time is short. This agent can be administered without expensive or elaborate equipment, nevertheless it requires at least a double yoke with oxygen and nitrous oxide tanks and a breathing bag and mask. The margin of safety with regard to the anesthetic concentration and the toxic or fatal concentration is not very wide. Nitrous oxide is contraindicated in associated head injuries, severe anemias or reductions in vital capacity, cardiac decompensation and hypertension. Premedication requires additional time and does not eliminate all the dangers or contraindications. The usual procedure in the use of nitrous oxide with the inexperienced and even sometimes the experienced anesthetist is to produce cyanosis and cerebral anoxia and then proceed with a struggling, excited, gasping, cyanotic individual until the desired result is obtained. The specific therapy for an excess of the agent is the inhalation of oxygen.

Ether

Ether will produce perfect relaxation for the time required to obtain and maintain reduction,

regardless of its length. It is easily administered even by the inexperienced, requires no elaborate equipment and has a wide margin of safety. The induction time is relatively long and spasm, coughing and vomiting are quite common. Vomiting is undoubtedly one of the most underestimated and overlooked dangers of anesthesia, especially during the administration of the inhalation agents. The average patient coming into the hospital or office for emergency treatment of a fracture has eaten within one to six hours previous to the time of fracture, and many are intoxicated. Inhalation of vomitus in these patients is fatal more often than is appreciated, and even when not fatal the morbidity is well worth careful consideration. With ether, emergence time is long and the patient usually requires some degree of hospitalization. It should not be used in the presence of x-ray or fluoroscopic equipment. It is contraindicated in diseases of the respiratory tract, kidney, liver and certain metabolic diseases. There are no specific therapeutic measures for overdosage. The usual resuscitative measures of oxygen therapy, artificial respiration, the intracardiac administration of adrenalin and respiratory stimulants are of some value.

Pentothal

A discussion of the intravenous barbiturate anesthetics should include a consideration of Evipal as well as of Pentothal, but owing to the almost exclusive use of the latter in this series of cases and because of the advantages it possesses, the former will be omitted.

Pentothal will produce sufficient relaxation for the reduction of any type of fracture, and by the fractional method of administration will maintain this relaxation for a sufficient length of time for the most difficult reduction and the application of any type of maintenance apparatus. The induction time is very short—one to three minutes—and is usually unaccompanied by excitement or struggling. The danger of the aspiration of vomitus is present with the intravenous anesthetics as well as with the inhalation agents, but the percentage of occurrence in the former is so small as compared with that of the latter agents that Pentothal holds a distinct advantage in this respect. In this series of administrations only 1 case of vomiting is recorded.

The emergence time is short and permits the patient to be accompanied home within thirty minutes to one hour. Pentothal is easily administered without elaborate or expensive equipment.

This method of producing anesthesia should not be employed by anyone who is not familiar with its use. Its margin of safety is to a great extent

dependent on the skill of the administrator. However, in the hands of one who has had sufficient experience to make him as competent with Pentothal as with the inhalation methods, the method is less hazardous than is the inhalation of ether or nitrous oxide, and produces better results than does local infiltration.

The contraindications are few, and are limited almost entirely to severe respiratory depressions and infections and extensive disease of the liver. Respiratory depression to a greater or lesser degree is always an accompaniment of barbiturate anesthesia, and it is to a large extent because of this that Pentothal is adjudged as dangerous by some competent anesthetists. The inexperience of the administrator is more evident in respect to the production of respiratory depression than in any other phase of Pentothal administration. In this series in only 1 case was respiratory depression severe enough to warrant oxygen therapy. However, on account of this ever present possibility extreme care must be exercised at all times to ensure thorough and complete oxygenation. The maintenance of a patent airway, and the administration of the oxygen if necessary, will reduce this complication to a minimum. For short procedures it is believed that damage to the liver is not of major importance if oxygenation is complete.

One of the additional advantages of this method is that there is no danger of fire or explosion if it is used in the presence of x ray or fluoroscopic equipment.

There is one indication for the use of Pentothal that is often overlooked. This occurs in fractures with an associated head injury. Most of these patients have multiple contusions and abrasions about the face with contaminated bleeding wounds, fractured skulls and evidence of damage to the brain. Nitrous oxide is definitely contraindicated. Ether will produce struggling, excitement, vomiting and increased intracranial pressure, with possible aggravation of the initial head injury. The mask or cone will have to be applied over a potentially septic and devitalized area. Pentothal is the agent of choice in these cases. The traumatized area is not touched, there is no struggling, intracranial pressure is not increased and the scalp and face wounds can be treated at the same time, or after the fracture has been reduced, without necessitating removal of the apparatus for induction. If severe respiratory depression from increased intracranial pressure exists, it may be unwise to use Pentothal, but still in many cases of this type it may be the least of the evils. These are not ambulatory cases, but they deserve some consideration in this discussion.

With all precautions taken in the use of the agents discussed there will still be an irreducible number of complications, but that this number will be lowest with the use of Pentothal has been our experience.*

TECHNIC OF ADMINISTRATION

In the use of Pentothal an adequate dose of atropine may be used as a premedicament. This can be administered intravenously if time does not permit the attainment of its effect subcutaneously. Atropine will minimize the bronchial constriction that may be produced by the anesthetic agent. Because of the danger of respiratory depression, some apparatus for the administration of oxygen with a breathing bag and mask and one of the analeptics should be available. No set dosage or scheme of administration can be prescribed, so that it is believed best to establish a standard method and to vary it according to the individual reaction. In the average adult, with the patient counting aloud, 3 cc. of a 5 per cent solution of Sodium Pentothal should be given in the first half minute, followed by a pause of thirty seconds to allow for circulation and maximum effect. Two cubic centimeters may be administered in the next half minute. By this time counting has stopped, the patient is usually asleep and respirations are slightly depressed. This is the point where it is necessary to be certain that the patient is well oxygenated. Reduction should not be undertaken until there is no reaction to pinching the skin and the respirations are regular and of good amplitude. Reduction with the patient in too light a plane of anesthesia may result in respiratory spasm and arrest. With the needle still in situ additional drug is administered in 1-cc. or 2-cc. fractions as required. From the above standard each patient will vary according to age and general physical condition. At present, Pentothal is not used in very young children.

RESULTS

During the first ten months of 1939, Pentothal was used for approximately 300 patients who were admitted, diagnosed, x-rayed, treated and sent home as ambulatory patients. These patients were anesthetized by members of the orthopedic and surgical services under the supervision and direction of the anesthesia service. There were no fatalities. As mentioned above, only 1 patient required oxygen therapy and an analeptic for respiratory depression and this patient had an uneventful recovery. Vomiting was present in only

Cyclopropane has been purposely omitted from this discussion because it requires elaborate and expensive equipment and a experienced administrator and is not available in the majority of outpatient clinics and offices.

1 case, and occurred during emergence with the patient in full possession of the cough reflex. No patient required hospitalization because of the anesthesia. Insufficient relaxation was never the cause of a poor orthopedic result. In a small proportion of cases readministration was necessary because of inadequate reduction, but in no case did a patient refuse to undergo a repetition of the anesthetic.

SUMMARY

The advantages and disadvantages of local, nitrous oxide, ether and intravenous barbiturate anesthesia for use in the reduction of fractures in

ambulatory patients have been discussed. The dangers of the inhalation of vomitus and of respiratory depression, the necessity of thorough oxygenation at all times and the need of an experienced administrator have been emphasized. Penothal seems to be the ideal anesthetic for this type of fracture because it produces sufficient muscular relaxation for reduction, can be continued as long as necessary, has short induction and emergence times, is easily administered and has an adequate margin of safety with few contraindications, while specific therapy for an excess of the agent is available.

THE TREATMENT OF ATROPHIC ARTHRITIS WITH ESTROGENIC SUBSTANCE*

ABRAHAM COHEN, M.D.,† ALFRED W. DUBBS, M.D.,‡ AND ABRAHAM MYERS, M.D.§

PHILADELPHIA

NOT uncommonly the menopausal and postmenopausal eras of a woman's life are associated with some degree of arthralgia. The condition may range from vague fleeting joint pains to a classic hypertrophic, atrophic or mixed arthritis. The hypertrophic and the mixed forms are in our experience by far the most frequent. Whether these changes are directly due to the endocrine readjustment of this period we do not know, but that they play some part in causation of the arthritides seems obvious.

Many authors (Mazer and Israel,¹ Scholler, Dohrn and Hohlweg,² Stone,³ Pratt and Thomas,⁴ Holmes,⁵ Champy,⁶ Kuipers,⁷ Recknagel,⁸ Cawadiaz,⁹ Kahimeter,¹⁰ Marchionini,¹¹ Fleischhaus¹² and Hall¹³) have reported encouraging results with the use of estrogenic substance in the treatment of hypertrophic joint disturbances occurring coincidentally with the menopause, either natural or induced.

We have also had similar experience in the treatment of such cases. After a careful analysis of results obtained we have concluded that although improvement was noted in the majority of our cases, it was of a general nature. Joint conditions per se, if secondary to hypertrophic changes, remained the same unless posture and weight were corrected.

A study of the climacteric symptoms, which were the general phenomena benefited by estrogen, with the exception of hot flashes, revealed a striking similarity to those experienced by the sufferer from atrophic arthritis. They were sweating, circulatory disturbances, mental depression, asthenia and paresthesias (numbness and tingling) of the extremities and nervousness.

Although the menopausal function is uncertain, it is generally conceded that with the cessation of ovarian function the anterior lobe of the pituitary gland becomes overactive, with a resultant influence on the endocrine tissues which come within its sphere. The objective signs of this period are supposedly the direct result of such action. The subjective phenomena mentioned are the well-known climacteric symptoms, and are probably due to a disturbance of the sympathetic nervous system. In discussing arthritis, Pemberton¹⁴ states that one can conceive of the sympathetic nervous system, and indeed the nervous system as a whole, as congenitally unstable.

This similarity of climacteric symptoms with those of sufferers from acute and chronic atrophic arthritis, together with reports that cases of atrophic arthritis were benefited by pregnancy,¹⁵ a period during which the estrogen level is high, led us to believe that estrogenic substance might have a place in the therapy of atrophic arthritis.

Twenty-three cases of arthritis, 17 being of the atrophic and 6 of the mixed (atrophic and hypertrophic) type, were treated with large doses of

estrogen.* Twelve of the patients experienced a distinct improvement in joint symptoms while under this therapy, 5 of these had symptoms of active menopause, which were coincidentally relieved (Table 1). Three patients noted some improve

TABLE 1 Summary of Results

| TYPE OF ARTHRITIS | NO. OF CASES | CLINICAL RESULTS | | | |
|---------------------------|--------------|------------------|----------|-------------|------------|
| | | IM PROVED | BE LAYED | UNIM PROVED | MADE WORSE |
| Atrophic | 17 | 7 | 3 | 6 | 1 |
| Atrophic and hypertrophic | 6 | 5 | 0 | 1 | 0 |
| Totals | 23 | 12 | 3 | 7 | 1 |

ment and then relapsed. Seven patients noted no improvement, general or local, and 1 said she was worse. Eighteen patients were supposed to have passed a normal or a surgically induced menopause, but 6 of these still had active menopausal symptoms. Of the total of 11 patients with active menopausal symptoms, 7 noted improvement in the joint symptoms as well as in the subjective phenomena related to the menopause, while 4 noted a general improvement with no effect on the joint symptoms.

The duration of treatment ranged from one week to three months. The total dosage of estrogenic substance varied from 50,000 to 850,000 IU (international units). Individual doses ranged from 10,000 to 100,000 IU.

In the beginning the patient was given an intra muscular injection of 10,000 IU daily and when improvement was noted the interval was reduced to once weekly. If no improvement was noted the dose was increased gradually to 100,000 IU. After three or four such doses, if no change was noted, treatment was discontinued.

Twelve young sufferers from atrophic arthritis (moderately advanced) without menstrual disturbances were used as a control. Each was given 50,000 IU of estrogenic substance daily for one to three weeks. None showed any response.

Hall¹² has recently shown that following the castration of 71 women, 53 suffered from arthralgia rather than true arthritis, and that of 40 who were adequately treated with estrogenic substance 70 per cent responded to the extent of almost complete relief of menopausal and arthralgic symptoms.

It must be noted here that in some cases the giving of estrogenic substance had to be continued over a period of many months in order to maintain improvement, while in others improvement was noticed within a short time and continued even after treatment had been stopped.

Our criteria for the diagnosis of atrophic arthritis accorded with the classification set forth by the American branch of the *Ligue Internationale Contre le Rhumatisme*.¹⁶

The following cases are typical of those which showed improvement following estrogenic therapy.

CASE 1. K. M., a 49-year-old white woman presented herself at the clinic complaining of pain and stiffness in the neck, knees, elbows and feet. Onset had occurred 3 years previously with stiffness and numbness in the fingers, noticed chiefly on rising in the morning. Gradually the other joints became involved. Definite aggravation of symptoms was noted with changes in the weather.

The menstrual function ceased 4 years previous to admission following the removal of a pelvic tumor. The patient was still suffering from an occasional hot flash.

At physical examination the patient walked with slight difficulty. The elbows were partially flexed. The body weight was 138 pounds. The temperature, pulse and respirations were normal. The eyes, ears and nose were normal. The tonsils were diseased, the teeth and gums appeared to be normal. The neck showed 50 per cent limitation of motion in all directions. There was considerable tenderness on pressure over the cervical vertebrae. The shoulder motion was limited to 45° abduction in both. The elbows were flexed but could be extended to about 70°. There were swelling and tenderness in both wrists. The hands were somewhat swollen and slightly tender. The hands showed a tendency toward ulnar deviation with spindly shaped deformity in the middle and index fingers on the right, and in the middle and ring fingers on the left. The knees were swollen and tender to touch and motion. The suprapatellar bursae were thickened and distended with fluid. The cervix was negative. The diagnosis was atrophic arthritis of the cervical vertebral joints, knees, elbows and feet.

Estrogenic substance, 10,000 IU, was given daily from June 22 to July 6. At the end of this course of treatment the patient stated that the stiffness and pain in the joints were markedly diminished. Medication was withheld for 1 week, after which the patient reported back to the clinic complaining of a return of pain and stiffness in all the previously involved joints.

Estrogen substance, 10,000 IU, was given daily from July 20 to 26. Again improvement was noted. It was discontinued until August 12, and during this period the patient was decidedly worse. Ten thousand international units of estrogen was again given daily until August 17. At this time a tonsillectomy was done and the patient was not seen again until September 28 at which time she reported a return of symptoms in the knees.

CASE 2. E. E., a 43-year-old white woman complained of stiffness and pain in the arms, legs, knees and hips. One year previously she had started to have pain, swelling and redness involving both knees, with a gradual spread to the other joints. All the symptoms were worse in the morning and were definitely aggravated by changes in the weather. The menstrual function had ceased 2 years previously and since then the patient had had frequent hot flashes.

At physical examination the head and neck were normal except for diseased teeth and tonsils, and tenderness with slight limitation of motion in the cervical vertebrae. The heart, lungs and abdomen were normal. The extremities showed no contractures, but there were spindly shaped deformities of the fingers and swelling in the wrists.

*Estrogen, in the form of Progynon, was supplied through the courtesy of Schering Corporation, Bloomfield, New Jersey.

and knees. The gynecological examination was negative. The diagnosis was atrophic arthritis of the knees, hips, elbows and shoulders.

Ten thousand international units of estrogenic substance was given daily from May 4 to 17. At the end of the 1st week of treatment there was distinct improvement in the upper extremities, but the knees seemed to be worse. Some nausea was noted in the morning. The hot flashes and headaches were markedly improved. At the end of the 2nd week a marked improvement was noted in all the joints, the patient was again able to go up and down stairs, and slept far better than prior to the taking of estrogen. Estrogen was discontinued until May 25, at which time 10,000 IU was administered weekly for 4 successive weeks. At the end of this course the patient still complained of some pain and stiffness in the right hand. A tonsillectomy was done June 22. The patient was not seen again until July 20, at which time the joints were all improved. She stated, however, that her general well being was not so good as when she was receiving estrogen.

SUMMARY AND CONCLUSIONS

Our experience in treating hypertrophic arthritis coincident with the menopause by the administration of estrogen has led us to believe that the benefits, though striking, are of a general systemic nature. The joint condition per se must be treated by mechanical readjustment and weight reduction in order to bring relief.

The present study was made in an endeavor to determine whether estrogenic substance, which has such a marked effect on the subjective symptoms of the menopause, would in any way influence the strikingly similar symptoms of atrophic arthritis.

The rationale of this therapy was based on the assumption that both these symptom complexes probably result to some extent from a disturbance of the sympathetic nervous system.

The results suggest that little benefit is obtained in women suffering from atrophic arthritis who have no disturbance in menstrual function.

Atrophic arthritis occurring concomitantly with the menopause was benefited in a sufficient percentage of cases to suggest that this form of therapy has a definite place in the treatment of such cases of atrophic arthritis.

REPORT ON MEDICAL PROGRESS

FUNDAMENTAL MISCONCEPTIONS INVOLVING
CLINICAL PATHOLOGY*

WILLIAM T. SALTER, M.D.†

BOSTON

BECAUSE clinical pathology is merely the adaptation of the fruits of fundamental research to concrete problems in medical practice, it is often difficult to define the precise limitations of the subject. In last year's report for this journal,¹ the subject matter was limited chiefly to practical procedures and precautions. The present report, on the contrary, will concern somewhat more fundamental aspects, which, although less practical, are probably more important. The scientific bases for many well known laboratory procedures are constantly changing, particularly as new methods enrich the basic sciences, and accordingly those interested in clinical pathology must continually adopt new methods and ideas.

PLASMA PROTEINS

One such revision of knowledge involves the plasma proteins. In the last few years, fundamental studies of the nature of these proteins have shown clearly that the usual clinical subdivision into albumin, globulin and fibrinogen is extremely gross. With the development by Tiselius² of an apparatus which permits accurate study of the migration of molecules in an electric field, it soon became obvious that the serum protein consisted of many more individual fractions than had been supposed. The classification of these is still tentative, but a brief synopsis of two hypothetical, isolated, characteristic plasmas (normal and nephrotic) is given in Table I.

This table is not intended to give possible variations or the range of normal values. Actually, the relative proportions of the various fractions are more constant in normal plasma than are the absolute levels. Further details may be found in the paper of Longworth, Shedlovsky and MacInnes.³

Although it has been suspected for a long time that there is more than one globulin in plasma, the albumin hitherto has been considered to be an entity. It is striking that recently even very pure, crystalline serum albumin has been resolved by this method into two components, as described by Luetscher.⁴

When albumin globulin ratios are determined by the usual salting-out procedures, the actual fractions involved are mixtures. The albumin fraction contains a moderate amount of globulin,

TABLE I Fractions of Plasma Protein

| FRACTION | OLD CLASSIFICATION | | NEW CLASSIFICATION | |
|-------------------|--------------------|------------------|--------------------|------------------|
| | NORMAL PLASMA | NEPHROTIC PLASMA | NORMAL PLASMA | NEPHROTIC PLASMA |
| | gm per 100 cc | gm per 100 cc | gm per 100 cc | gm per 100 cc |
| Albumin | 4.00 | 0.37 | — | — |
| Alpha | | | 0.70 | 0.11 |
| Beta | | | 1.30 | 0.76 |
| Globulin | 2.10 | 2.83 | | |
| Alpha | | | 0.46 | 1.47 |
| Beta ₁ | | | 0.31 | 0.16 |
| Beta ₂ | | | 0.53 | 0.92 |
| Gamma | | | 0.78 | 0.28 |
| Fibrinogen | 0.40 | 0.50 | 0.40 | 0.50 |
| Totals | 6.50 | 3.70 | 6.50 | 3.70 |

and the globulin fraction contains much albumin, as shown by Butler and his associates.^{5, 6} With the new apparatus of Tiselius⁷ it is possible to obtain a sort of spectrum, which pictures the distribution of various protein fractions in a given plasma, much as a photospectrograph analyzes the transmission of various wave lengths of light by a certain solution. The protein spectrum so obtained resembles a silhouette of a mountain range. The various peaks in the outline indicate various individual protein fractions. Moreover by measuring the area subtended by each peak, one learns the concentration of the fraction in question. Obviously, the area of the total silhouette represents the total protein concentration. The silhouette or spectrum diagram can be obtained readily by using an automatic camera as described by Longworth⁸ and by Philpot.⁹ The latter's method is the simpler and less expensive.

When this optical analysis is made of abnormal plasmas, interesting results are obtained, as described by MacInnes and Longworth¹⁰ and by Longworth, Shedlovsky and MacInnes.³ Moreover, the urinary protein can be subjected to similar studies, but, surprisingly enough is often normal in composition, no matter what the state of the plasma protein.

Detailed studies of abnormal plasmas have shown that characteristic changes occur in vari-

*From the Theodike Memorial Laboratory, Second and Fourth Medical Services (Harvard) Boston City Hospital, and the Department of Medicine, Harvard Medical School, Boston.

†Assistant professor of medicine, Harvard Medical School; junior visiting physician, Boston City Hospital.

ous clinical syndromes. In febrile conditions the alpha globulin tends to be increased. In the nephrotic syndrome, in myeloma and in obstructive jaundice, there may be increase in the beta globulin, which is associated with blood lipids. Immune bodies usually appear in the gamma fraction.

Luetscher¹¹ has summarized some of these changes as found in several well-known clinical syndromes. He has shown that when the colloid osmotic pressure drops because of loss of albumin, compensatory increases occur first in the beta globulin and later in the alpha globulin. The gamma globulin is low in the nephrotic syndrome but this is of little osmotic consequence as compared with the changes secondary to the severe loss in albumin. In terminal glomerulonephritis the plasma may approximate the normal. In a case of amyloid disease (with tuberculous lymphadenitis) the albumin was decreased and the gamma globulin increased. This same type of distortion was also found in cirrhosis of the liver, both in the plasma and in the ascitic fluid.

The apparatus involved is somewhat expensive and at present is available only for research purposes. Because the protein spectrums so obtained are highly characteristic, however, it seems very possible that eventually the method will be used routinely in clinical diagnosis and in order to follow clinical progress precisely. Meantime, it provides overwhelming evidence of the crudeness of the plasma-protein analyses now in common use.

PIGMENTS OF HEMATOGENOUS NATURE

Another revision is needed in the field of certain pigments related to, or derived from, hemoglobin.

"Porphyrinuria" For several decades, clinicians and pharmacologists have discussed the reddish color of urine which sometimes follows the taking of drugs or even may occur spontaneously. Recent work has focused attention on the excretion of porphyrins and other pigments in the urine of patients suffering from deficiency disease. For example, Spies and his associates¹² have described a red pigment, produced by the action of heat on ethereal extracts of urine from cases of pellagra. In this disease and in several other conditions, the pigment has been offered as evidence of porphyrinuria. Recently, however, Watson^{13, 14} obtained from cases of alcoholic pellagra a red pigment that had some of the characteristics of indirubin, a derivative of indol. Subsequently, he concluded that the pigment described by Spies, though differing from indirubin, was

nevertheless an indol derivative having the characteristics of urochrome.

Meiklejohn and Kark¹⁵ have confirmed these observations, working with urine from cases of endemic pellagra not associated with alcoholism. In these cases there was no abnormal excretion of true porphyrins. Such urines, however, may contain indican. Furthermore, they may show a characteristic urochrome reaction through the oxidation of ether-soluble indol derivatives in the presence of hydrochloric acid. It will be remembered that indol has long been recognized as a breakdown product of the amino acid tryptophane. When indolacetic acid is treated with nitrous acid, the solution turns a deep cherry red, and the pigment so formed has properties closely resembling the pigments now described by Spies¹² as "porphyrin-like substances."

These investigations, therefore, make it seem probable that marked pellagra may occur without porphyrinuria. The test used by Beckh, Ellinger and Spies¹⁶ to test urinary porphyrins has no direct connection with porphyrins, and these are better identified by some other procedure, for example, that of Brugsch and Keys.¹⁷

Cyanosis of Chemical Origin Last year I¹⁸ pointed out that the cyanosis induced by sulfanilamide presented a fundamental paradox. Briefly put, the difficulty was that the oxygen-combining capacity of the blood of very cyanotic patients is nearly normal, although the spectroscope shows the presence of methemoglobin and sometimes of sulfhemoglobin. In recent work, Webb and Kniazuk¹⁸ have made the following suggestions: the amount of methemoglobin or sulfhemoglobin present may or may not be enough to account for the cyanosis, and the cyanosis might conceivably be due largely to a colored oxidation product of the sulfanilamide. Such a colored product has not been identified precisely, although Marshall and Walz¹⁹ have suggested "aniline black," and Fox, Cline and Ottenberg²⁰ "a purple dye." Wendel and Wendel²¹ on the contrary, find that in some cases the amount of methemoglobin may be sufficient to explain the cyanosis, and that combinations of these pigments may occur. It seems more likely to Webb and Kniazuk that the contaminating pigments are not due directly to the interaction of sulfanilamide with natural substances in the body. They favor the explanation that a chaotic response by the hematopoietic system may yield abortive pigments related to hemoglobin. Indeed, Rimington and Hemmings²² found high values for ether-soluble "porphyrins" in the urine of patients treated with the drug.

Nevertheless, one cannot lightly dismiss the pos-

sibility of a dye that arises directly from the drug, because Barkan²⁷ has noted that under certain conditions blue sulfanilamide derivatives may appear which are readily reduced to the colorless state or re-oxidized to the colored form. Apparently nascent hydrogen peroxide is responsible for the formation of such blue oxidation products. The problem is complicated by the fact that, in the laboratory, blood samples from treated patients may continue to form methemoglobin after the blood is drawn, probably owing to the presence of a sulfanilamide derivative. Furthermore, solutions of sulfanilamide may turn black, especially if exposed to light. Thus various factors may combine to produce clinical cyanosis in a given patient.

With regard to sulfhemoglobin, it must be remembered that the widespread impression that this pigment contains sulfur has not yet been confirmed. It is clear that hydrogen sulfide—in the presence of oxygen—forms a green pigment from normal blood pigment *in vitro*, and it is therefore possible that the intestinal hydrogen sulfide produces sulfhemoglobin in the body. According to Barkan and Schales,²⁸ it also remains possible that this pigment belongs to the family of pseudohemoglobins, which normally accompany the hemoglobin within erythrocytes as intermediates between hemoglobin and bilirubin.²⁹ Like hemoglobin, the pseudohemoglobins contain unaltered globin, but the prosthetic group is an iron containing hemin derivative in which the porphyrin ring is open, and hence unlike hemoglobin. The pseudohemoglobins are the source of the "easily split off" iron of blood cells described by Barkan,²⁸ which, unlike hemoglobin, is ionized by weak acids. In the normal red cell, pseudohemoglobin combines reversibly with oxygen and carbon monoxide, as does hemoglobin, but the pseudohemoglobin has a higher affinity for carbon monoxide.

Due to the effect of carbon monoxide on the pseudohemoglobin, as Barkan and Berger²⁷ pointed out, cases of acute carbon monoxide poisoning show a remarkable decrease in the amount of "easily split off" iron in the blood even when so little carbon monoxide is present as to render spectroscopic examination or routine chemical tests worthless. Indeed, Schwarz and Deckert,³⁰ in a report on 80 cases of such poisoning noted that this change persisted for several days after the acute episode. Consequently, this test may prove to be important as a confirmatory diagnostic procedure, because blood is often drawn for laboratory analysis so late that the patient has already excreted most of the poisonous gas.³¹

HEMORRHAGE AND VITAMIN K

The prevention or control of hemorrhage, which complicates so many clinical conditions, has been modified considerably by the discovery of vitamin K. No longer, for example, does the busy intern routinely prepare jaundiced patients for operation by repeated injections of calcium salts, nor does he rely on the routine clotting time³² as a yardstick of operability in such cases.

The rapid accumulation of knowledge about vitamin K has led to the development of several methods for determining the concentration of prothrombin in the blood. For purposes of clinical investigation a rather complicated technique is required, as exemplified by the method of Warner, Brinkhous and Smith.³³ For a routine clinical laboratory the test worked out by Quick, Stanley Brown and Brinkhoff³⁴ is simple, and sufficiently reliable for ordinary clinical therapy. The test is read by noting the time at which a clot or definite threads of fibrin appear in transparent plasma. This plasma is first prepared from citrated blood, and the clotting mechanism initiated at a given instant by adding an excess of calcium and thromboplastin. The thromboplastin may also be freshly prepared from rabbit's brain by titration with acetone.³⁵

Less accurate, but very convenient, is the "bed side test" of Smith, Ziffren, Owen and Hoffman.³⁶ In this procedure a crude preparation of thromboplastin, extracted from rabbit or ox brain or lung, is used to indicate clotting in a small tube, which is tilted every few seconds. A normal blood is first tested, and the number of seconds (T_1) required for clotting is noted. The test is then performed in a second tube with the unknown blood (T_2). The "clotting activity" is calculated from the percental ratio of the two time intervals. In general hemorrhage will occur when the activity is only a third to a half of normal.

Because the prothrombin time is the net result of several factors, Warner³⁴ has pointed out that various methods may yield discrepant answers. Quick³⁴ also has emphasized the calcium factor in quantitative determination of prothrombin. The methods mentioned here, however, are serviceable in indicating the presence of a tendency to hemorrhage, and in cases of jaundice are definitely superior to the classic clotting-time methods, which may remain normal until hemorrhage is evident clinically. Even in babies from three to seven days old, the concentration of prothrombin may be estimated readily, as shown by Quick and Grossman.³⁷

Although jaundice is the chief indication for the employment of this test it is also of interest in other conditions which affect the accumulation of

vitamin K. Indeed, this "anti-hemorrhagic vitamin of the chick," first described by Dam and Schonheyder,^{37 38} is frequently lacking to a serious degree in patients suffering from a variety of disturbances. Among these are the chronic diarrheas similar to sprue, regional ileitis, hemorrhagic disease of the newborn and various diseases of the liver. In treating these conditions with natural vitamin (K₁ and K₂), with phthiocol or with synthetic substances like 2-methyl-1,4-naphthoquinone, it is desirable to control the effectiveness of therapy by laboratory observations because the response varies considerably from patient to patient. It also varies somewhat with the method of administration, as described by Butt, Snell and Osterberg³⁹ and, more recently, by Snell and Butt.⁴⁰

IODINE IN BLOOD

In thyroid disease and related endocrinological disturbances, there has long been confusion between the terms hyperthyroidism, thyrotoxicosis and Graves's disease. Because it has been impossible to measure directly increased thyroid hormone in the blood, many clinicians have used these words synonymously. During the past decade, however, micromethods have been developed for determining blood iodine which yield consistent results. Although the normal blood iodine concentration is probably less than 10 microgm per 100 cc (0.000,01 per cent), various investigators have attempted to divide even this small quantity into organic and inorganic fractions. The presumption is that the organic fraction reflects the concentration of circulating hormone. Long series of determinations by Gutzeit and Parade⁴¹ in Breslau, by Curtis and Puppel⁴² in Ohio and by Perkin and his collaborators^{43 44} in Boston all indicate that an approximate estimation of circulating hormone will be feasible in the near future.

Already there are strong indications that we must revise our way of thinking about Graves's disease by strictly separating clinical "toxicity" and chemical "hyperthyroidism" as two distinct variables which need not necessarily run parallel to each other. Both Curtis, Cole and Phillips⁴⁵ and Perkin and Hurxthal,⁴⁶ for example, have reported cases of Graves's disease in which nervous symptoms, eye signs, goitrous swelling and tachycardia (or auricular fibrillation) were severe, whereas the blood-iodine concentration was normal. In these patients, as might be expected, the basal metabolic rate tends to be relatively low. I⁴⁷ have recently pointed out that blood iodine may be fractionated into inorganic iodide, an or-

ganic iodine combination like thyroxine and an organic iodine combination like di-iodotyrosine. These three fractions occur in the thyroid gland itself, and much fundamental work remains to be done in correlating the three blood levels with the state of the gland.

At the moment, accurate blood-iodine determinations are available in only a few large clinics, but it seems clear that the information thus acquired is destined to be of considerable diagnostic help in those instances in which the basal metabolic rate is elevated for reasons which are primarily extrathyroidal. Neurovascular asthenia, cardiac decompensation, malignant disease and tuberculosis are among the conditions which frequently frustrate attempts at differential diagnosis.

The determination of total iodine may be inadequate because the ingestion of iodide may increase this blood level more than tenfold. In such cases, however, the organic fraction may even diminish. Consequently, the tendency is to study organic or hormonal iodine concentration.

It is not possible to give here detailed descriptions of the micromethods now available. Useful information has been obtained in this country by the procedures of Trevorrow,⁴⁸ of Perkin,⁴³ of Curtis and Puppel⁴² and of McClendon.⁴⁹ Full descriptions of methodology may be found in books by McClendon,⁴⁹ Elmer⁵⁰ and myself.⁵¹

BENZOL AND LEUKEMIA

Another misconception that has cost hematologists many hours and afforded law courts much grist for the oratorical mill is the differential diagnosis between benzol poisoning and aleukemic leukemia. It is now clear that the two conditions often merge, one into the other, and just as senile keratoses of the skin merge into epitheliomas, there is no sharp delineation between the two states. In a highly illuminating trilogy⁵² published recently and entitled "Chronic Exposure to Benzene (Benzol)," the clinical effects of benzol poisoning are discussed by Hunter and Gall and Brickley. These papers lead to the conclusion "The evidence that chronic exposure to benzene produces leukemia in human beings is still incomplete, but it is accumulating at a rate and to a volume which command serious consideration." The investigators cite cases in which patients previously exposed to benzol have been said to have had early myelogenous leukemia, low-grade chronic lymphatic leukemia or possibly early multiple myeloma. When the bone marrow of such patients was studied, it was found that,

contrary to classic opinion, hyperplastic marrow predominated over aplastic marrow. The degree of anaplasia and the number of mitotic figures strongly suggested malignant tissue. This type of bone marrow was closely similar to that described by Martland in cases of chronic radium poisoning, which also leads to prolonged stimulation of reproductive activity accompanied by arrest of maturation.

The case histories of these patients, supplemented by bone-marrow studies, are extremely interesting and serve to emphasize the increasing importance of bone marrow biopsy in the differential diagnosis in obscure cases. In particular these studies indicate forcibly that leukemia may be due to a tumor of the bone marrow in which benzol plays the role of a carcinogen. The obvious inference is that benzol is not the sole cause of leukemia, but that possibly other substances arising from physiological sources may lead similarly to leukemia.

One still hears discussions of blood findings which stress the occurrence of myelocytes in the blood as pathognomonic of leukemia. Indeed in a recent address to the American Society of Clinical Pathologists, the chairman⁶² said

Does anyone doubt that the presence of myelocytes and other immature cells of this series in predominant numbers establishes a positive diagnosis of myelogenous leukemia regardless of a clinician's opinion?

This statement is colored by an administrative problem concerning professional status which does not concern us here. Suffice it to suggest that hematological specialists constantly stress the fact that myelocytes may occur in considerable numbers in several conditions other than leukemia, for example in pneumonia. Furthermore in myeloid metaplasia the usual therapy for leukemia may prove fatal as pointed out by Jackson⁶⁴. In short, I believe that the diagnosis of leukemia should never be made without a comprehensive survey of all the clinical data available. In some cases, it may be necessary even to examine the bone marrow before the correct diagnosis is reached.

TYPES OF ELECTROPHOTOMETER

A common misunderstanding encountered in electrophotometry at present involves the respective optical arrangements of the single-cell and double-cell instruments. Last year I¹ called attention to the development of electrophotometers for clinical use and described the general method for the single-cell type. Since that time a number of technical details have been investigated further and consequently somewhat higher precision and reliability are now possible. Some of these prob-

lems have been described by Summerson⁶⁵. He believes that for very careful work it is desirable to use a nul point instrument in which two photoelectric cells are employed. Thus one can measure in rapid succession the color effect of the unknown and the standard, respectively. With this arrangement the depth of solution may be varied, and very high accuracy attained, as shown by Goudsmit⁶⁶. Furthermore, the relation between the scale reading and the concentration is independent of the depth of color in the system, so that the experimental accuracy is limited chiefly by the sensitivity of the photoelectric cell. The measurements are, however, independent of the actual value of the photoelectric-cell current, and measure the difference in voltage between a working and a reference cell. Indeed, the photoelectric properties of the reference cell are not used.

The use of the so-called calibration curve is eliminated, and indeed is not advised. For very accurate work, an unknown (X) may be compared directly with a standard (S), in much the same fashion as in visual colorimetry, by comparing the two readings (Rx and Rs). Since $SX = Rs Rx$, it follows that the unknown concentration

$$X = \frac{R_x S}{R_s}$$

On the other hand, the two-cell instrument may be used for many purposes with constant depth of solution. Under this condition, the concentration is read on a logarithmic scale which is often directly proportional to the concentration, so that direct readings can be made when the scale is properly numbered. Interchangeable standardized test tubes are used to hold the unknown solution or standard, the latter is made up simultaneously with the unknown.

Because such readings are not influenced by fluctuations in the light source, there is no need for storage batteries or constant-current regulators. The current can be adjusted adequately by means of a simple potentiometer, controlled through a low sensitivity galvanometer. This is true because the reference cell and the working cell react in the same way to minor fluctuations in power supply. In addition, the two-cell type measures the ratio between intensity in the same manner as the Dobosq visual colorimeter, which has greater accuracy than is obtained by using the difference between intensities, as is done in the one-cell type. In routine chemical readings only a single adjustment is required for each reading and for many substances the concentration may be read directly on the logarithmic scale.

A selective light filter which has a spectral width

of 50 to 75 millimicrons is used to screen out all light except that of the wave band to be measured. Such filters are available for most of the common colorimetric procedures.

The experience of the past year in various clinical and research laboratories has amply confirmed previous enthusiasm for a method which measures color in a tube merely on the insertion of such an interchangeable test tube into the instrument. The chief uncertainty at the moment is which type of instrument to choose.

SUMMARY

In conclusion, then, it is evident that in applying the methods of laboratory medicine to individual bedside problems, the oversimplified tests in common use may yield misinformation unless interpreted in the light of basic facts. Furthermore, because no basic fact can be trusted as being completely true, it is clear that constant vigilance must be the price of reliance on laboratory methods and their interpretation. This article has reviewed a few of the more recent revisions in medical tests and theories which have been necessitated by revisions of fundamental science.

CASE RECORDS OF THE MASSACHUSETTS GENERAL HOSPITAL

ANTEMORTEM AND POSTMORTEM RECORDS AS USED
IN WEEKLY CLINICOPATHOLOGICAL EXERCISES

FOUNDED BY RICHARD G. CABOT

TRACY B MALLORY, M.D., *Editor*

CASE 26041

PRESENTATION OF CASE

A fifty five year-old unmarried woman was admitted to the hospital complaining of indigestion.

The patient stated that she had always experienced occasional attacks of "indigestion" until fifteen years before admission when, following a large meal of steak and onions, she suddenly developed a severe attack of right upper abdominal distress with the vomiting of yellow gall. Following this attack of a few hours duration she was well until eight years before admission when she entered this hospital because of menorrhagia. She was given a sterilizing dose of x rays to the ovaries, and had one period a month following this treatment but no vaginal bleeding since that time. She was well until three years before entry when she again began having attacks of indigestion three to four hours after eating rich foods, particularly fatty foods. These attacks occurred every six weeks, were characterized by a preliminary bloated feeling causing her to loosen her corset, then a dull intermittent pain in the right upper quadrant of the abdomen, which was not crampy but made her quite restless. This dull ache always started in the right upper quadrant, sometimes went through to the right side of the back, and on one occasion three weeks before admission radiated to an area between the shoulder blades. The pain usually lasted about thirty minutes and was relieved by vomiting. Following this she noted a residual soreness in the right upper quadrant for twenty four or forty-eight hours. About six weeks before entry the patient noted the onset of periumbilical "soreness" and a feeling of gaseous distention and rumbling. There were no real abdominal cramps and no particular change in bowel habits except slight constipation. Three weeks before admission, following one of these attacks, the urine was dark, the stools were light colored, and she became slightly jaundiced. At no time did she experience chills and fever. She was examined in the Out Patient Department no masses were palpated. A Graham test showed a gall bladder which filled but contained many stones. An appointment was given for admission to the hospital. Since that time the

patient had noted a separate midabdominal steady soreness, which was aggravated when lying down. She had lost 10 or 12 pounds in the six week period before entry. She had experienced no tarry or bloody stools and no genitourinary symptoms during the present illness.

The physical examination revealed a well developed, moderately obese woman in no apparent distress. The examination was negative except for the presence of a firm, non-tender, grapefruit sized mass located in the left side of the abdomen. The mass could be moved quite freely from low in the left lower quadrant to a point opposite the umbilicus. The liver edge descended two fingerbreadths below the costal margin on deep inspiration. Pelvic examination was negative.

The temperature, pulse and respirations were normal.

Examination of the urine was negative. The blood showed a red-cell count of 4,420,000 with a hemoglobin of 60 per cent (Tallqvist), and a white-cell count of 7100. One stool examination gave a ++++ guaiac test. The serum van den Bergh test was normal, indirect, and the non protein nitrogen 23 mg per 100 cc. A blood Hinton test was negative.

A gastrointestinal series showed moderate delay of the passage of barium through the small intestine. All films, taken hourly, showed a loop of small intestine in the left midabdomen, which did not change during the two-hour examination. The loop was wide, irregular in outline, retained barium and coincided with the palpable mass which lay over the wing of the left ilium. A barium enema was negative. A chest plate was negative.

On the ninth day an operation was performed.

DIFFERENTIAL DIAGNOSIS

DR. HORATIO ROGERS May we see the x ray films?

DR. FELIX FLEISCHNER The Graham test shows the gall bladder filled with dye and small stones. The chest is negative. The examination of the gastrointestinal tract shows a loop of small intestine moderately dilated, and several films taken at hourly intervals show the same loop unchanged. Even when the loop was empty one can see an air bubble which corresponds in size and shape to the barium filled loop on the previous films. This loop coincides with the palpable mass. The examination of the colon is negative except for a shallow indentation in the descending portion. There is moderate delay of the passage of barium through the small intestine.

DR ROGERS Could you say anything from these films about the mucosa of that loop

DR FLEISCHNER There is complete destruction of the mucosa in the stiffened loop in the center of the palpable mass. There are some more loops probably fixed to the surface of the mass without appreciable destructive lesions.

DR ROGERS The first part of the history is consistent with gall-bladder disease. The subsequent course and the x-ray films show that there were gall stones in the gall bladder. Six weeks before admission a new set of symptoms began, which apparently increased until admission. Presumably six weeks before admission examination showed no mass, but on entry there was a very definite mass. The symptoms which she developed in the periumbilical region were related to the mass by x-ray study, and there is no reason to suppose that the mass was not the cause of the symptoms. These later symptoms are characteristic of small-intestine disease. Therefore, we must choose between one diagnosis to explain two quite distinct types of symptoms, or more than one diagnosis to account for both.

If we must make one diagnosis and connect the gall-bladder disease, which we know she had, and the small-intestine disease, which we also know she had, it seems hard to think of anything but a gallstone ileus. There are a good many factors here that help, perhaps to build up a misleading picture of gallstone ileus. The fact that the obstruction was never complete and progressive is characteristic of gallstone ileus, because a stone which is not big enough to obturate the intestine may be compressed by spasm, thus causing intermittent obstruction. A ++++ guaiac test on one occasion is consistent with mucosal erosion from any cause. The general good condition of the patient is more consistent with something which is of rather recent onset than with a chronic disorder. The fact that the gallstone does not show in the x-ray films is not conclusive. Dr Franklin G. Balch, Jr, found that in half the cases in our series which were x-rayed the stone did not show. The age group is characteristic of gallstone ileus. But the x-ray picture is very disturbing if we try to make that diagnosis. There appears to be a firm mass, and destruction of a rather large area of mucous membrane, which is not at all characteristic of recent gallstone ileus.

If we have to make two diagnoses, gall stones will be one in any case, and to that we must add some form of tumor or some form of infection or something quite different. If we consider inflammatory disease plus gall-bladder disease, we are confronted with a normal white count, a normal chart and symptoms not suggestive of inflammatory disease.

The inflammatory diseases we might consider would be regional ileitis or possibly x-ray enteritis from the previous x-ray treatment, which I do not believe was sufficient to produce this picture after eight years. We do not know how near this lesion was to the cecum, but the story is not that of regional ileitis. By its duration it should have been in the acute phase, and yet the patient had no elevated white count or fever.

The tumors that we should have to consider would be benign tumor of the intestine, possibly with intussusception, of which there is no evidence by x-ray, and malignant tumor. Carcinoma is rare as a primary lesion of the small intestine. It could be metastatic, but in that case there would probably be abdominal carcinomatosis, and this woman had not been sick long enough with intestinal symptoms to make one think that she could have had partial obstruction of the small bowel by carcinomatosis and nothing more to show for it than we have here. The pelvic examination and the barium enema you will remember were negative.

Another malignant tumor of the small intestine is lymphoma. I cannot rule out lymphoma. The sudden appearance of the mass would be against it. If we have to alter something to make this diagnosis fit, I should be inclined to change that observation in the Out Patient Department that "there was no mass." The patient was moderately obese, and perhaps the mass really was there. The laboratory data are consistent with lymphoma. The x-ray picture is very suggestive of it. So that I think the diagnosis lies between gallstone ileus with a degree of damage to a loop of small bowel which I cannot explain, and primary lymphoma of the small intestine, plus unrelated gall bladder disease. I submit these two diagnoses in that order, remembering that, statistically at least, a single diagnosis is more likely to be right than a multiple one.

DR FLEISCHNER I think the x-ray findings of an infiltrating lesion in a loop of the lower jejunum or upper ileum rule out gallstone ileus.

DR AUBREY O. HAMPTON Besides that the gall bladder filled with dye and the stones are too small.

DR ROGERS That is not an entirely valid objection because I have seen a gallstone taken out of the ileum which had focal concretions that increased it to the size of a golf ball, yet when the mass was cut the stone itself was rather small.

DR ARTHUR W. ALLEN Dr Rogers is perfectly correct in thinking that this mass was probably present at the time the patient was in the Out Patient Department, because, in seeing this woman,

the mass was much more easily palpable at some times than at others. We must remember that she came to the hospital with a typical attack of gallstone colic, and naturally, attention was directed toward the region of the gall bladder. At operation we found at least three coils of jejunum and a segment of descending colon all matted together. One would like to arrange a multiple stage resection for this amount of disease in the intestine if possible, but we could not orient ourselves clearly enough to warrant doing any kind of short-circuiting procedure as a preliminary operation. It was necessary to follow the jejunum down from the ligament of Treitz, and free the first loop from the main mass. There was an interim of normal bowel for approximately 60 cm., and then we came to the main tumor. It was also necessary to free the colon from the tumor before we could be sure that the mesentery of the affected small bowel could be safely removed. The upper loop of jejunum we believed was involved by contiguity, as was the descending loop of colon. The mesentery of the jejunum in the region of the tumor was tremendously thickened. It was the thickest mesentery I believe I have ever seen. It seemed to be very edematous. It was found that by resecting a segment of jejunum about 90 cm. long we could extirpate, in one piece, the segment containing the main tumor and that portion of jejunum which we believed was involved by contiguity. Then continuity was established by aseptic end-to-end suture. The involved colon was transected between clamps placed through a stab wound in the left flank, and an obstructive colostomy done. The patient is having the spur of the colostomy crushed at the present time. She has made a very good recovery. I should have liked to look into the pelvis since she had been previously radiated for vaginal bleeding, but I did not believe we should explore the abdomen to that extent, nor did we do much about looking at the gall bladder or bile ducts. We found no evidence in the abdomen of extension of this disease beyond the area I have described.

CLINICAL DIAGNOSIS

Tumor of small intestine (? lymphoma)

DR. ROGERS'S DIAGNOSES

Gallstone ileus?

Lymphoma of intestine, plus unrelated gall bladder disease?

ANATOMICAL DIAGNOSIS

Malignant lymphoma (stem-cell type) of jejunum

PATHOLOGICAL DISCUSSION

DR. TRACY B. MALLORY. The various specimens that we received showed an extensive area of neoplastic involvement of the small bowel, which was thickened and dilated and had the appearance often described as 'rubber hose.' There was extension of the tumor into the mesentery, and enlargement of a number of nodes deep in the mesenteric root. The tumor had obviously invaded the serosa of the large bowel and another loop of jejunum. The gross appearance was very characteristic of lymphoma of the bowel and on microscopic examination we made that diagnosis. It was the least differentiated type of lymphoma, one which we have been recently calling the stem-cell type. There is no question that it was very rapidly growing although I do not believe it was quite as rapid as the history might indicate.

DR. EDWARD A. GALL. May I ask the roentgenologist how many intrinsic tumors of the bowel produce localized dilatation in the area of involvement?

DR. JAMES R. LINGLEY. Twenty five per cent of tumors of the bowel produce dilatation rather than obstruction. I do not know of anything else that will dilate a localized loop like that.

DR. MALLORY. You do not see it with inflammatory lesions?

DR. LINGLEY. Not so far as I know.

DR. MALLORY. This patient is now being referred to the Tumor Clinic, and I presume is going to have postoperative radiation.

DR. J. H. MEANS. Do you suppose there was lymphomatous involvement of the liver? It came down two fingerbreadths. Is that common with gall-bladder disease or stone?

DR. MALLORY. Normal livers not infrequently come down two fingerbreadths.

DR. ALLEN. At operation we looked at it particularly, and it appeared to be normal.

DR. MALLORY. Involvement of the bowel occurs not infrequently in the course of general lymphoma, but I think more often lymphoma of the bowel is a sharply localized disease, we have reason to believe it was in this case.

DR. MEANS. It may be followed by general lymphoma later?

DR. MALLORY. Yes. You may confidently expect such an event if there is no treatment, and usually in spite of treatment, although we have had a number of very long cures following surgical removal of lymphomas of the gastrointestinal tract.

DR. ALLEN. We took out all the mesentery of the involved bowel. We believed we could do this with safety, but we were cutting through edematous tissue. Is the mesentery involved in

the process or was the edema due to lack of lymph drainage to the area?

DR. MALLORY There was considerable extension of the tumor into the mesentery, but I do not believe that all the swelling represented tumor. As you said, it was edematous.

DR. MEANS I should like to check on the physical examination. Do you state definitely that you have seen a good many cases in which the liver edge was definitely felt two fingerbreadths below the costal margin and in which the liver was perfectly normal at necropsy?

DR. MALLORY Yes

CASE 26042

PRESENTATION OF CASE

A fifty-year-old woman was admitted to the hospital complaining of pain in the abdomen, back and legs.

Two years before admission the patient successfully underwent a Miles operation for carcinoma of the rectum, performed in an outside hospital. Following this procedure she was well, with a normally functioning colostomy opening, until six months before entry, when she began having difficulty in regulating the discharge from the colostomy opening. She also began experiencing "various pains" in the abdomen, back and legs, which were not explained organically, and showed "extensive ecchymosis" with a positive tourniquet test. The bleeding and clotting times and complete laboratory studies were allegedly normal. Roentgenograms of the pelvis and lumbar spine and a gastrointestinal series were negative. She was treated on the basis of having had an anxiety neurosis with a strong cancer phobia, and was placed for a while in a psychiatric institution. Therapeutic adjuvants were sedatives, analgesics and, occasionally, codeine. Trascentin was given for the relief of intestinal spasm, and Theelin injections, with the thought that her symptoms were aggravated by the menopause. She showed some improvement in her outlook and ability to control her symptoms while in the hospital. Her condition remained approximately the same following discharge until six weeks before admission, when she consulted another physician and complained of numbness of the feet and legs, — saying they felt as though they were blocks of wood, — of mental depression with fits of crying and of pain in the lower back. She was wakeful, noisy and even hysterical. Examination failed to show any evidence of metastases, and there were no neurological signs in her extremities. The colostomy opening appeared satisfactory and functioned well,

although she complained of abdominal distress. These symptoms continued. Beginning nine days before entry, tarry, and on one occasion bloody, stools were noticed. X-ray films of the lumbar spine and pelvis were again negative. She was then given 0.5 cc of snake venom for its psychological effect and with the thought that it might relieve her pain if there was any. She was given 1 cc on each of the following days, during which time she developed purpuric spots on the arms and chest. A blood examination four days before admission showed a red-cell count of 2,300,000 and a white-cell count of 7100, the smear was not remarkable. The next day the red-cell count was 1,700,000, the hemoglobin 30 per cent, the bleeding time 3.5 minutes, and the clot retraction normal. The urine examination was negative. She received two 500-cc transfusions of citrated blood, and the red-cell count rose to 2,800,000 one day before admission.

Physical examination revealed a fairly well developed, disoriented, pale woman, who was somewhat unco-operative and negativistic. The heart was slightly enlarged to the left, and there was a blowing systolic murmur heard to the left of the sternum. The blood pressure was 195 systolic, 100 diastolic. The lungs were essentially negative. Palpation of the abdomen was unsatisfactory. The patient was incontinent of urine during the examination. She complained of such intense pain in the left leg that she would barely let the examiner touch it. She could raise it, although it seemed to be more flaccid than the right. The biceps, triceps and radial reflexes were exaggerated and equal. The right patellar response was exaggerated and greater than the left, which seemed slightly less active than normal. Visualization of the bowel, through the colostomy opening, with a proctoscope was unsatisfactory, the instrument could be passed only for a distance of 8 to 10 cm. A bimanual examination, with a right hand finger in the colostomy opening and the left hand in the vagina, revealed no masses suggestive of tumor, although there was a smooth, hard, fixed area behind the cervix which did not feel cancerous.

The temperature was 98°F, the pulse 80, and the respirations 20.

Studies of the blood revealed a red-cell count of 3,200,000 with 78 gm of hemoglobin (photoelectric-cell technic), a white-cell count of 10,700 with 86 per cent polymorphonuclears, and an otherwise negative smear. The urine was negative except for a ++ albumin test. The blood ascorbic acid was 0.9 mg per 100 cc, and the blood Hinton test was negative. Roentgenograms of the colon were unsatisfactory because the tube could not be introduced far enough into the colostomy opening.

ing. It passed directly downward for a distance of 20 cm where it met obstruction, apparently a kink in the bowel as it turned upward, as fast as barium was introduced it returned through the stoma. One short length of bowel, apparently sigmoid, was demonstrated. Portal films of the skull showed no evidence of metastatic cancer, the pineal gland was calcified and in normal position.

The patient's condition became steadily worse, both psychically and physically. She died on the eleventh hospital day.

DIFFERENTIAL DIAGNOSIS

DR. WYMAN RICHARDSON: When I first glanced at this case I decided it was very obscure. After looking more carefully I decided it was very simple. If it is simple, I may be right. If it is obscure, I shall have to get someone to make the diagnosis for me.

First, I want to take up the question of whether in the beginning this patient had a blood dyscrasia. Since thinking about it, I have been wondering what dyscrasia meant. I looked it up yesterday and the definition I saw was a morbid condition due to a toxic agent in the blood, which is not the ordinary connotation of the word, but may in fact, in this case, be a fairly good definition. In regard to ecchymoses, purpura and bleeding tendency, did she have some type of purpura? She certainly did not have thrombopenic purpura because of normal bleeding time, normal clot retraction and normal smear, if we can assume that there were platelets in the smear. She could not have had scurvy—I think there is nothing suggestive in the history, and the blood ascorbic acid was high enough to rule out symptoms due to scurvy. That leaves us with a toxic purpura. It might have been due to drugs. The purpura might be due to snake venom. I know that there are snake poisons that are hemolytic whether some might produce purpura, I do not know.

In regard to some primary blood disease involving the red cells, she did have an anemia which, from the levels of hemoglobin that we are given was essentially normochromic. There was no evidence of severe hypochromia, on that basis I think we can rule out chronic blood loss. If the anemia was entirely due to blood loss it must have been a very severe hemorrhage in order to reduce the red-cell count to 1,500,000 or a little over. If it was severe hemorrhage, one would expect a reduction in the blood pressure to shock levels, but the blood pressure was 195 systolic, 100 diastolic. Loss of blood might be a factor in the anemia

but it does not seem to fit the blood picture as a whole. There is nothing else in the record to suggest a primary anemia. We have to leave it out. Is there anything to suggest a leukemic process or any other primary blood disease? I do not see it.

Now I should like to go back and read the first two sentences of the history. "A fifty-year-old woman was admitted to the hospital complaining of pain in the abdomen, back and legs. Two years before admission the patient successfully underwent a Miles operation for carcinoma of the rectum, performed in an outside hospital." My plan is to forget the rest of the record and assume that the patient had a recurrent carcinoma of the pelvis with pressure on the lumbosacral nerves and that she did have serious pain. I think it is perhaps fortunate, at least if I am right, that I was not able to see the patient. Hind sight is better than foresight, and without seeing the patient it is flying in the face of Providence to say that the patient did not have recurrent disease in the pelvis. That is what I am going to say. If so, why did she become disoriented and go downhill so rapidly? She did not die of hemorrhage, because the red count tended to come up if anything. What did she die of? Cerebral metastases? Certainly this is not the death of cerebral metastatic disease. It is well known that a tumor in the pelvis may interfere with certain functions, and particularly with the function of renal excretion, and it seems quite possible that this recurrent tumor interfered with the function of the bladder. We know that she was incontinent. Was she incontinent because she had a big dilated bladder, with stasis, and did she have a marked uremia from that? It is rather difficult to say that in this case in view of all the examinations that were done. One would think a pelvic examination, particularly, would have revealed a large distended bladder, but nevertheless I suggest that as a possibility.

The other possibility it seems to me is that the patient had obstruction to the ureters and, with that, a uremia. In any case I am quite confident that the patient did have uremia and that that explains why there was a marked hypertension on the first examination in the face of very severe anemia. That also might explain the anemia itself or part of it. Frequently with severe uremia there is a normocytic, normochromic anemia, sometimes macrocytic. There is one other statement in the examination. A "bimanual examination revealed no masses suggestive of tumor although there was a smooth hard fixed area behind the cervix which did not feel cancerous." I do not know but I suppose postoperative scar

tissue may feel hard To my point of view it might well have meant cancer

They did not determine the prothrombin level Might liver disease explain the bleeding tendency? That is going too far afield There is no evidence of metastases in the liver, and I think it is foolish to bring that in at all

I am going to say that the patient had recurrent carcinoma in the pelvis I am not quite sure why the bleeding from the gastrointestinal tract was so marked, but it is known that if one has uremia, one may get bleeding from the gastrointestinal tract, with or without ulcers One cannot say much more about it than that I am going to predict that she had recurrent carcinoma in the pelvis with uremia due to obstruction to urinary outflow, either because of bladder dysfunction or ureteral obstruction That is what I call the simple answer

DR. TRACY B MALLORY Do you care to voice an opinion as to whether she had schizophrenia? I cannot prove the point

DR. RICHARDSON I should hate to give that opinion without at least talking to the patient

CLINICAL DIAGNOSIS

Recurrent carcinoma of rectum?

DR RICHARDSON'S DIAGNOSES

Recurrent carcinoma in pelvis

Uremia due to bladder dysfunction or ureteral obstruction

ANATOMICAL DIAGNOSES

Carcinoma of sigmoid, with extension to pelvic tissues and obstruction of ureters

Hydroureter, bilateral

Hydronephrosis, bilateral

Hypoplasia of bone marrow

Bronchopneumonia

Arteriosclerosis, aortic, coronary and cerebral, slight

Infarction, left optic thalamus

Operative scar resection of rectum and colostomy

PATHOLOGICAL DISCUSSION

DR. MALLORY The postmortem examination did show carcinoma which massively involved the pelvis It may or may not have been recurrent. Our feeling was that it probably was not but was a cancer in a new area of bowel In the sigmoid, about 10 cm from the colostomy opening, was a tumor which involved all layers of the intestinal wall and which had all the appearances of a primary carcinoma This was unquestionably the source of the continued intestinal bleeding It was in direct contact with a mass of tumor which completely encircled the pelvis and unquestionably involved all the nerves that passed through the pelvis and also both ureters Above the point of obstruction the latter were markedly dilated, and there was bilateral hydronephrosis. So far as the anatomical evidence can be offered for uremia I believe she had it I am not entirely certain about the cause of the anemia Certainly the renal insufficiency was a possible factor On the other hand, the bone marrow was quite markedly hypoplastic, more so than I can remember having seen in ordinary renal insufficiency, so that I am tempted to believe that some other toxic agent may have caused the hypoplasia of the bone marrow The brain was negative except for moderate arteriosclerosis of the vessels at the base and a small area of softening in the left optic thalamus

SUBSCRIPTION TERMS: \$6.00 per year in advance, postage paid, for the United States; Canada \$7.00 per year; \$8.50 per year for all foreign countries belonging to the Postal Union.

MATERIAL for early publication should be received not later than noon on Saturday.

THE JOURNAL does not hold itself responsible for statements made by any contributor.

COMMUNICATIONS should be addressed to the *New England Journal of Medicine*, 8 Fawcett Boston, Massachusetts.

REPORTS ON MEDICAL PROGRESS

THE new series of progress reports has already entered into its second year, and the *Journal* takes this opportunity of expressing its appreciation to the fifty odd contributors who have made and continue to make this feature possible. Various letters to the editor and numerous requests for reprints, received from all parts of the country by the authors, attest to the popularity of these reviews, and the editorial staff is firmly convinced that this method of commenting on current medical trends should be continued. In the scheme for the current year, new topics will replace those of last year in which advance has been, of necessity, relatively slow, and large topics, such as cardiovascular disease and arthritis, will be covered from a somewhat different point of view. The effort to make the reports of value to the prac-

ticing physician has apparently been successful, but the *Journal* welcomes suggestions in regard to titles and to the method used in presenting the material.

For those physicians who wish to obtain the reports in bound form, arrangements for reprinting were made with Little, Brown and Company, of Boston, and the book, *Reports on Medical Progress—1939* has already been offered for sale at a reasonable figure. As a year book the volume is unique for it covers progress in all branches of the medical profession in a way that should appeal not only to the physician in general practice but to the specialist who wishes to keep in touch with fields of medicine other than his own.

SOCIAL HYGIENE DAY

FEBRUARY first has been designated as Social Hygiene Day. Throughout the country there will be meetings, radio talks and demonstrations to inform the public as to the work which the national and state societies are doing.

What, exactly, is "social hygiene," and in what activities are the societies that bear its name engaged? Hygiene, according to Webster, is the science of the preservation of health, the limiting adjective, "social," may be interpreted broadly as the relation between men and women. Social hygiene, therefore, may be defined as the science of preserving a healthy attitude toward the sexual aspects of life. Although it has to do essentially with the sexual relations of mankind, it is not limited to a consideration of the procreative act alone. Its purpose is the development of a sound attitude toward all the problems connected with sexual life.

The activities of the societies for social hygiene branch out in various directions. One important function is the prevention of gonorrheal diseases through the education of youth. The actual treatment of these infections is left very properly in the hands of physicians, clinics and the state boards of health. Another function is the establishment of personal counseling services to which individuals who are unhappy because of sexual maladjustment can apply for help. The prob-

lems encountered are those that trouble many unmarried people, as well as those of maladjustment in marriage, which if unchecked lead to the divorce court. Many of the latter are not primarily related to sexual matters alone, but have to do with economic causes, uncongenial employment and other stresses that crack the solidity of married life. Other activities of social-hygiene agencies vary from studies of the care of syphilitic mothers to the closing of unsavory places of entertainment.

The measures employed for these purposes are largely of the educational type. The distribution of literature, such as the pamphlet, *Growing Up in the World Today*, and various others on syphilis and gonorrhea, is supplemented by the lending of books from a carefully chosen library. Lectures are given on syphilis and gonorrhea, on boy and girl interrelations, on preparation for marriage and on marriage adjustment. Some five hundred of these lectures are given annually by the Massachusetts Society for Social Hygiene, the audiences consist of clubs of boys or girls, students in high schools, normal schools and colleges, church groups, parent-teacher associations and women's clubs. During the past year, the Massachusetts society, in conjunction with the Committee on State and National Legislation of the Massachusetts Medical Society, sponsored a bill which required premarital examination for the detection of communicable diseases, including syphilis.

The Massachusetts Society for Social Hygiene is affiliated with the American Social Hygiene Association and in turn has affiliations with several local social-hygiene committees—in Springfield, Holyoke, Pittsfield and Cambridge. For the work done in Greater Boston, the society receives support from the Community Federation, of which it is a member agency. From this fund and from other sources it derives the money with which to carry on a broad educational program. It is impossible to estimate the actual returns from the expenditure of this money, one can only point to the increased demand for lecturers and institutes and to the awakened interest shown by women's clubs and employers in the problems created by genitoinfectious diseases and in the measures that may be taken to lower their inci-

dence. Furthermore, the requests for advice from the personal counseling service are more than can be met.

There is a demand for services such as the social-hygiene societies are equipped to render. It is to be hoped that the desire for economy now spreading throughout the country will not result in a curtailment of their activities.

ADDITIONAL SERUMS FOR THE TREATMENT OF PNEUMOCOCCAL PNEUMONIA

THE facilities available to Massachusetts physicians for the treatment of pneumococcal pneumonias continue to increase. An announcement in this issue of the *Journal* states that, in addition to therapeutic serums for three additional types obtainable under the usual restrictions, those for all other types of pneumococci will be supplied by the Massachusetts Department of Public Health in those cases in which the organism is found in the blood, spinal fluid or peritoneal cavity.

Sulfapyridine alone is finding a place in the treatment of pneumococcal pneumonia, but in certain cases therapeutic failures will result if specific serum is not also used. Certainly, when the organism is found to be causing a bacteremia, meningitis or peritonitis, every useful method should be used to save the life of the patient, and it is gratifying to know that serums will be easily obtainable for such cases in the future.

MEDICAL EPONYM

ASCHOFF BODIES

These structures were first described by Ludwig Aschoff, then professor of pathology at Freiburg, in an article entitled "Zur Myocarditisfrage (The Problem of Myocarditis)" which may be found in the *Verhandlungen der deutschen pathologischen Gesellschaft* (8: 46-53, 1904). A section is translated as follows:

We succeeded in finding peculiar nodules which seemed to be specific for rheumatic myocarditis. These nodules were clearly marked, it is true, in only two cases of recurrent endocarditis, but corresponded in their location exactly to the cellular proliferation found in other cases. They usually lay in the neighborhood of small or medium sized blood vessels and often showed the most intimate relation to the adventitia of

these vessels, or there was found simultaneous involvement of all layers of the blood vessels such as has been described in arteritis nodosa. The nodules are extremely small, at most submillimetric in size, and arise through the collection of notably larger elements with one or more abnormally large slightly notched or polymorphic nuclei. The aggregation of cells often occurs in the form of a fan or rosette. The periphery is formed by the large nuclei; the center by the confluent protoplasm of the cells which often seems to stain weakly or otherwise appears to be a necrotic mass. The fan-shaped foci recall when superficially observed, the tiny necrotic areas of gout with the peripheral cell mantle as they are frequently found in gouty kidneys.

FATAL PUERPERAL SEPSIS FOLLOWING NORMAL DELIVERY

Mrs. M. A., a twenty-nine year-old primipara, was admitted to the hospital February 3, 1912, in active labor. The expected date of confinement was January 22, her last period having begun on April 15, 1911.

The patient's family and past histories were not recorded. There had been no complications during this pregnancy.

The physical examination on entry was normal. The lungs were clear and resonant, there were no rales. The heart was not enlarged, there were no murmurs. The pelvic measurements were normal. The baby was in an OLA position, and the head was engaged.

After ten hours of active labor the baby was delivered spontaneously. There were no lacerations. The mother's condition following delivery was good.

On the fourth postpartum day, she complained of a sore throat and had a chill, with an elevation of the temperature to 104.4°F. The abdomen was tender in both lower quadrants. The lochia was thick, dark, and foul smelling. The following day, February 8, there was marked tenderness and spasm in the lower abdomen. Moderate distention was relieved by enemas and flaxseed poultices. An intrauterine douche of sterile water was given, followed by one of alcohol. Morphine was used for pain. By February 12, nine days after delivery, the patient had developed a mass in the left lower abdominal quadrant. Vaginal examina-

tion disclosed a mass the size of a coconut, which was tender and non-fluctuant.

During the course of the next ten days the patient seemed to recover from the peritonitis but her temperature and pulse remained elevated. Her abdomen was flat, soft and non-tender. Vaginal examination revealed that the pelvic mass had involuted and was the size of a hen's egg. The right vault was free. The patient was given strychnine, digitalis and caffeine for stimulation. Brandy was administered freely.

The heart by February 27, twenty-four days post partum, was enlarged and evidently failing rapidly. The pulse was of poor quality. A diagnosis of myocarditis was made. Two days later she developed pulmonary edema and died. The diagnoses were streptococcal tonsillitis, parametritis and septicemia.

Comment. This case was another which occurred in 1912 during a hospital epidemic. It is interesting that the temperature did not rise until the fourth postpartum day. In such epidemics, infection may occur at any time during the hospital stay. A sterile douche was used with no more effect than we now know we should expect. In cases such as this one, in which the patient survives for as long as three weeks after the onset of the infection, recovery frequently occurs. In this case, not only did an apparent septicemia exist but also a parametric infection, as evidenced by the mass palpable in the left lower quadrant. Such masses should always be treated conservatively except those which develop into pelvic abscesses and hence require surgical drainage.

STATED MEETING OF THE COUNCIL

A STATED meeting of the Council will be held in John Ware Hall, Boston Medical Library, 8 Fenway, Boston, on Wednesday, February 7, at 10.30 a.m.

BUSINESS

1. Call to order at 10.30 a.m.
2. Presentation of record of last meeting (published in *New England Journal of Medicine* 221:699-703 1939).
3. Report of auditing committee and of treasurer.
4. Reports of standing committees and special committees.
5. Appointment of delegates.
 - a. To the House of Delegates American Medical Association for two years from June 1, 1940.
 - b. To the annual meetings of the five New England state medical societies in 1940.
 - c. To the Annual Congress on Medical Education and Licensure, American Medical Association.
6. Incidental business.

A series of selected case histories by members of the section will be published weekly. Comments and questions by subscribers are solicited and will be discussed by members of the section.

Councilors are asked to sign one of the two attendance books before the meeting. The Cotting Luncheon will be served immediately after the meeting.

ALEXANDER S. BEGG, *Secretary*

RESOLUTION BY THE MIDDLESEX EAST DISTRICT MEDICAL SOCIETY ON THE DEATH OF GEORGE NATHANIEL PLUMMER MEAD

George Nathaniel Plummer Mead, for forty-seven years an honored member of Middlesex East District Medical Society, died December 15, 1939. He was born in Concord, New Hampshire, February 18, 1859, and spent his boyhood there. He was graduated from Harvard College and Harvard Medical School, beginning the practice of medicine in Everett, Massachusetts. In 1896 he moved to Winchester, taking over the practice of Dr. Daniel March, and he remained a citizen of that town for the rest of his life.

Dr. Mead retired in 1929 after forty-one years of busy practice. He had the best interests of this society at heart and was always active in promoting medical progress. As the need for hospital facilities became more urgent he worked to establish in Winchester, first, a cottage hospital, which was opened in 1912, being sponsored by the Visiting Nurse Association, and, after that, the present modern, adequate institution. He was a good citizen, a loyal friend, a kind and generous man. His relations with his fellow practitioners were always guided by the highest medical ethics. He was respected and beloved by a large clientele. Therefore, be it

RESOLVED, That in the death of Dr. Mead this society record the passing of a loyal and honored member, a kind and generous friend.

MILTON J. QUINN,
RICHARD J. CLARK,
DANIEL C. DENNETT

DEATHS

LANE—WALTER A. LANE, M.D., of Milton, died January 21. He was in his sixty-eighth year.

Born in St. Louis, Missouri, he graduated from Hyde Park School in Chicago. He attended Dartmouth College and received his degree, cum laude, in 1899 from the Harvard Medical School. Dr. Lane served his internship in 1898 and 1899 at the Boston City Hospital and began practice in Milton in 1900. For a short time after receiving his degree he served as an assistant in chemistry at Harvard Medical School.

Dr. Lane was a fellow of the Massachusetts Medical Society and the American Medical Association, and was a member of the New England Pediatric Society. He served as vice president of the Massachusetts Medical So-

cety in 1932 and 1933, as chairman of the Committee on Public Relations from 1932 to 1937 and as a delegate to the House of Delegates of the American Medical Association in 1937. Dr. Lane had also served as president of the Norfolk District Medical Society and was a councilor from that district at the time of his death. He held memberships in various organizations, including the Dorchester Medical Club and the Boston Clinical Club.

Dr. Lane was a director and consultant of the Sharon Sanatorium and a member of the staffs of the New England Deaconess and Faulkner hospitals. From 1906 to 1924 he had served as Milton school physician.

His widow, a son and a daughter survive him.

McINTIRE—GEORGE F. McINTIRE, M.D., of West Barrington, Rhode Island, died January 9. He was in his seventieth year.

Born in Worcester, he received his degree from the Harvard Medical School in 1908. He was a fellow of the Massachusetts Medical Society and the American Medical Association.

Dr. McIntire was a founder of the Cambridge City Hospital and had practiced surgery in Boston and Cambridge.

NYE—HARRY R. NYE, M.D., of Leominster, died January 8. He was in his sixty-ninth year.

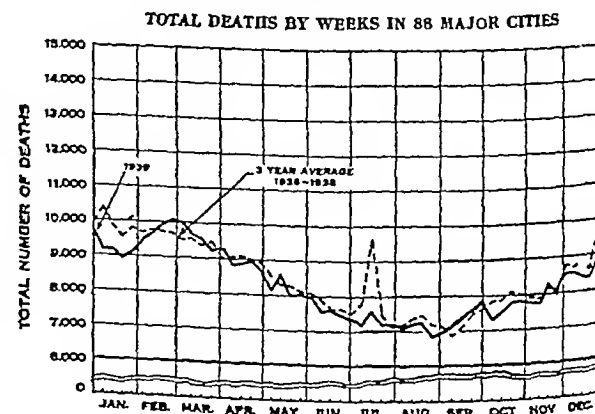

Born in Clarendon, Vermont, he received his degree from the University of Vermont College of Medicine in 1900. He served his internship at the Mary Fletcher Hospital in Burlington, Vermont, and had practiced in Leominster since 1907. Dr. Nye was a member of the staff of the Leominster Hospital for twenty-seven years.

He was a fellow of the Massachusetts Medical Society, having served as a councilor and also as past president of the Worcester North District Medical Society. He was also a fellow of the American Medical Association.

MISCELLANY

ANNUAL MORTALITY SUMMARY FOR 1939

Deaths in eighty-eight major cities during 1939 were 1 per cent over the 1938 figures, according to preliminary reports recently made public by Director William L. Austin, Bureau of the Census, Department of Commerce. The

infant death rate in these cities was slightly lower last year, compared with 1938.

Deaths in the eighty-eight cities totaled 429,419, compared with 424,348 reported for 1938. The weekly death totals reported in 1939 were consistently lower than the average totals for the preceding three years from January to July, inclusive. During the rest of the year, however,

they were closely similar to the averages of the preceding three years. The more favorable mortality record is due, probably to the smaller number of deaths from influenza and pneumonia during the winter and to the less extreme heat conditions during the summer.

The 25,713 infant deaths reported for 1939 represent a decrease of 1446 or 5.3 per cent, from the 27,159 reported for 1938. On the basis of estimated number of births there were, in 1939 41 infant deaths for each 1000 births. Although this figure is provisional it indicates a slight decrease in infant mortality when compared with the comparable provisional rate of 43 for 1938.

In the comparison of infant rates for different cities certain considerations must not be overlooked. The effect of differences in sex, age and racial composition of different cities must be evaluated before valid comparisons can be made. — *Bureau of the Census*

NOTE

At a recent meeting of the Harvard Chapter of Alpha Omega Alpha the following men from the fourth-year class of the Harvard Medical School were elected to membership: William Bacon, Addison G. Brenizer Jr., Thornton Brown, Bernard D. Davis, Francis T. Gephart, Bernard German, Charles H. Herndon, William F. Hickey, Edward Melman, Ernest Millard, Gordon S. Myers, Edward L. Pratt, Charles W. Sorenson and Thomas H. Weller.

CORRESPONDENCE

TREATMENT OF PNEUMOCOCCAL PNEUMONIA

To the Editor The Massachusetts Department of Public Health is making some changes in its program for the treatment of pneumonia and is providing under certain restrictions, serums of additional types. The new program includes:

1. The provision as in previous years of concentrated therapeutic (horse) serums for Types 1, 2, 5, 7 and 8 obtainable for the treatment of patients with infections due to one of these types, as determined by an approved typing laboratory.
2. The provision of concentrated therapeutic (rabbit) serums for Types 4, 9, 14 and 18 on the same basis as indicated above.
3. The provision of concentrated therapeutic (rabbit) serums for all other types for patients with *bacteremia meningitis* or *peritonitis* due to one of these types, the determination of which has been made by an approved typing laboratory.
4. A new circular describing the use of sulfapyridine; this drug appears to be valuable in the treatment of pneumococcal pneumonias.
5. A revision of the serum circular which is distributed with all specific horse serums provided by the department.
6. Revised case-report forms supplied by the department, which must be completed and returned to the department for all serum-treated cases.
7. New receipt forms, which must be signed by the physician receiving the serum and by the issuing agency.

The distribution of therapeutic horse serums will be continued as in previous years through typing labora-

tories. Therapeutic rabbit serums for Types 4, 9, 14 and 18 will be available only through the five typing laboratories from which Type 14 was supplied last season. All other therapeutic rabbit serums will be available from only two points: the Bacteriological Laboratory at the State House, Boston, and the Westfield State Sanatorium, Westfield.

The rabbit serums are being purchased, and the amount of money available for this purpose may not suffice for all demands. Therefore the continuation of this service will depend greatly on the conservation of funds effected through the prompt return of any unused serum.

Copies of the new sulfapyridine circular and the revised serum circular are being mailed to all physicians in the State and are also available at the approved typing laboratories. Additional copies of these circulars and a list of the laboratories at which the various serums may be obtained will be furnished by the department on request.

PAUL J. JAKMAUHI, MD
Commissioner of Public Health

State House
Boston.

HEALTH SERVICE, INCORPORATED

To the Editor It appears that a group of members of the Massachusetts Medical Society proposes to engage a charitable (?) corporation known as Health Service, Inc. incorporated organized for the purpose of selling medical and surgical services on a yearly basis to any and all who may qualify and are able to pay the annual charge. This is a mutual arrangement in that receipts are to be divided on a pro rata basis.

As with the Blue Cross organization, this service will doubtless soon be on the market, duly advertised through the newspapers and by agents who will solicit "business" throughout the community in stores, churches and factories and from door to door.

This movement should be seriously scrutinized for it promises to go far. It accepts all able-bodied individuals with incomes up to \$3500 per year but not those too poor to pay the fees, or those who fail to pass a physical test. These happily will still be taken care of by free clinics and general practitioners as usual.

This project should be scrutinized from three angles. The first concerns its relation to traditional standards of medical ethics as to advertising medical services and soliciting trade by ordinary business methods. It is obvious that if a group of five can do this, so can a group of three or two—or even one individual. Why may not I as a member of the Massachusetts Medical Society in good and regular standing engage a business agent to advertise and sell my services on a basis of annual fees in competition with the parent organization? I might strike legal difficulties to be sure, but that is not the question.

Secondly I may have to do something of the sort or give up the practice which I have acquired over a period of forty years, and which I see seriously jeopardized by a number of factors which hardly need to be mentioned.

Already under the Blue Cross, inroads are being made upon private practice, far more serious than has been generally recognized. The patient, I have frequently observed, having bought hospital insurance naturally picks out his hospital first and regretfully finds a doctor or surgeon assigned to him out of a staff from which his own doctor is excluded. The latter however is invited to call, and tries not to wince when the staff doctor takes all the fees. He is hopeful that his patient will come to

him later, but alas, the ethical (?) follow up letter, so popular now with most consultants, takes care of that. "In the interests of science," he is told, he should come in for a periodic checkup.

In the present state of competitive medicine one sometimes doubts certain philanthropic declarations. The general practitioner knows at least that his income has been derived largely from families in the lower income brackets—if \$3500 per year may be so termed. Apparently this entire class is to be taken right out from under his eyes—in the name of philanthropy—or else?

The question will be asked: Why not join the associates and get yours while the getting is good? And this, we must admit, smacks of worldly wisdom. Obviously, if others can do it, so can we—or I, and the course seems clear and inevitable—that is, if the Society and the State approve.

The third consideration (or perhaps this should be the first) is the welfare of the patient. This of course is put forward as the object and purpose of the whole business.

But *business* it appears to be, first, last and all the time. It cuts across and tends to jeopardize every legitimate private practice. It tends to a dictatorship in a close corporation organized upon a groundwork of rules and restrictions determined by the "higher ups." The average conscientious general practitioner, it seems to me, would feel himself often unpleasantly handicapped—let us say—by the three mile limit or being told just who and who not to use in consultation.

The very principle upon which good medical ethics has been based in the past seems to be at stake, namely, that the close friendly relation and personal responsibility between patient and physician should be guarded in every possible manner.

And so we hesitate. Is it because we are old fashioned and have a sort of lingering horror of introducing commercial methods into the practice of a profession to which one has given the better part of a lifetime? Do we see this kind of medical practice at the crossroads? Are we saying "goodbye forever" to that form of professional brotherhood which has characterized our cult from the days of Hippocrates? And are we entering now into a mad competitive struggle for the spoils of war—characteristic of a modern age which says—well—never mind what it says!

We well recognize that the whole problem revolves about the patient's best welfare. But this, I am sure, has always been the first consideration, with every general practitioner worthy of the name. Can we continue to trust that worthy instinct as we have done in the past and—will it be improved by regimentation?

WILLIAM W HARVEY, M.D

114 Fenway,
Boston

To the Editor As a practicing physician I am much interested in the letter with accompanying explanation of the health service plan, which appeared in the December 7 issue of the *Journal*. The letter suggests willingness to elucidate the plan further, if it is desired, and certainly more light is needed by some of us.

The scheme is described as a "budgeted health service plan," and in any such plan what one wants to know is how to pay the bill or how to budget whatever cost there may be. If I were a patient asking to know how to budget my already insufficient income, I should get very little assistance from the explanation in the *Journal*.

The analysis presented is so inadequate that one may

well question the soundness of the reasoning based thereon. The first sentence in the explanation begins "Because of the increasing cost of good medical care." The statement would be even more nearly true if it began

"Because of the increasing cost of government," or "Because of the increasing difficulty of keeping a job." Budgeting is important, but having an income to budget is more fundamental. What I mean is that much of the proposed action to enable people to pay for the cost of sickness is, although sometimes called too radical, as superficial as the polish on an automobile, when its efficacy in solving any real problem is considered.

Even if the statement began "Although the cost of medical care has been cut in half,"—which it has not been,—the conclusion of the statement—"many individuals today, who are self-supporting in the absence of sickness, are forced to become charity patients when confronted with serious illness"—would still be true. Also the explanation gives no actuarial basis for the scheme.

It is stated "Constructive criticism by the profession is eagerly desired." My only suggestion is that the proponents of the scheme state clearly in detail what it is they are going to do, and then we can all be in a better position to judge what they are likely to accomplish. Just now the statement fails to explain too much that needs expansion in order for a cautious person to have confidence in the practicability, much less in the substantial advantage, of the scheme.

STEPHEN RUSHMORE, M.D

520 Commonwealth Avenue,
Boston

To the Editor My attention has been called to Dr. David Sherwood's letter concerning Health Service, Incorporated, in the January 18 issue of the *Journal*. Dr. Sherwood thinks it is unfair for a lay organization such as Health Service to describe its service to the public in order that subscribing groups may be formed by those who wish to avail themselves of this service, and believes this situation deserves a protest.

The protest, I assume, is directed to Health Service, and I accordingly accept it. In so doing I wish to express the point of view of Health Service and, I believe, many of the lay public concerning certain questions which are of importance to the medical profession and which must necessarily be met in establishing a voluntary, self-supporting plan for budgeting the costs of medical care.

Payment of doctors' bills by families whose incomes are above the charity level often entails major financial difficulties. Many people in this income group delay in seeking medical care, curtail the amount of service sought or request charitable medicine from the profession or community. It is, therefore, to the interest of this portion of the public, to physicians and to the public which supports charitable medicine that the cost of distributing medical services be established in order to permit the provision of readily available and adequate medical care financed by those who receive it. If this is to be done on a voluntary basis, the consumers of the service must voluntarily form groups so as to provide an average cross section of health and illness. It is difficult to see how such groups can be formed, so that the medical service may be available to the public, without presenting to and discussing with the public the details of the service. If groups of the public want this service, it is to their interest to see that its availability is appreciated, for the suc-

cess of the service and therefore, the benefit to the public depend on the membership's being large enough to provide sound actuarial management.

To help clarify the question raised about solicitation attention may be called to the fact that Health Service, or the White Cross, was organized by lay representatives of the public in response to a demand voiced by numerous lay groups. After organization, Health Service sought appropriate arrangements with members of the medical profession for providing medical care to its subscribers. As has been commented on in the *Journal* the arrangement first contemplated was not approved by the Committee on Public Relations of the Massachusetts Medical Society and by other groups of physicians on the ground that it did not provide for adequate service. Accordingly, Health Service consulted a group of physicians concerning the manner in which adequate medical care could be provided to its subscribers. Finally, after this group had consulted with physicians engaged in various branches of medical practice, an agreement was entered into between Health Service, Incorporated and Medical and Surgical Associates for the provision of medical care to members of Health Service by duly licensed physicians. The major considerations determining the manner in which the medical care was to be provided and the details of the various agreements were presented to the medical profession in the December 7 and 21 issues of the *Journal*. The adequacy or quality of the medical care that should be available under these agreements has not I believe been questioned.

The question raised by Dr Sherwood was considered very carefully with the aid of legal and professional advice. Indeed, our appreciation of the importance of conforming to and protecting medical ethics was one of the major factors determining the final organization of Health Service, Incorporated. We believe that Health Service can describe the service which it makes available to the public and assist in the necessary organization of groups of subscribers in a spirit of rendering a non-profit public service without conflicting with or "undermining" medical ethics. We appreciate that the profession should be concerned lest desirable ethical principles be transgressed. At the same time, we would regret any unwarranted protest by the profession which might embarrass the ethical performance of a public service.

Other protests have reached us, which we believe also reflect a misunderstanding of our purpose. Some complaint has been made that the income limit of \$3500 per family is too high an income for eligibility to membership in this service. In considering this point it should be understood that this service is not intended for persons who fall into the class of those justly receiving charity medicine. It is interesting to remember that today in the City of Boston persons from families whose incomes are as high as \$50 a week or \$2500 a year are admitted to charity service. Since this is so a service for persons above the charity level should be permitted. There is, of course, the possibility that the distribution of costs under Health Service plan will permit persons now receiving charity medicine to become paying patients. But it is unreasonable to ask a financially self-supporting service to restrict its membership almost entirely to people who today when confronted with serious illness fall within the charity group. Different points of view should always be of interest because they are usually informative. It is, therefore, of interest that laymen are objecting to the arbitrary limit of \$3500 on the ground that their need of this service and their interest in its financial stability demand raising it to an appreciably higher figure.

The question of financial stability of such a service is of course a matter of no little concern to the profession for at least two reasons. First, unless such services are soundly financed, the remuneration of doctors is inadequate and the standards thus set may have a detrimental effect on professional remuneration in general. Second in so far as voluntary schemes fail financially the evidence supporting the need for governmental compulsory systems becomes more convincing to the public.

Those concerned with establishing this service have of course, been deeply concerned over assuring its financial soundness. This is an additional reason why the organization of the medical service is of prime importance. An effective administration unit is essential. The evidence that we have thus far been able to obtain clearly indicates that at the inception of the plan an unlimited choice of licensed physicians by subscribers is incompatible with solvency. The application of this latter principle would result almost certainly in such uneconomical functioning that a fair remuneration to the physicians rendering service to subscribers would be impossible. In so far as this might involve all physicians the interests of all physicians would be jeopardized. It is this aspect of the organization of such services either by the government or by medical societies that introduces a lack of economy and efficiency that renders such services radical ventures. We believe that such limitation in choice of physician as is contemplated in this service is in the interests of conservation of financial solvency and of the medical profession. If the White Cross plan succeeds and as the service grows, obviously a larger and larger percentage of the physicians in any community would be rendering service and receiving compensation under the plan and every effort will be made to give patients their choice of physicians and to give physicians the opportunity to accept as patients under this plan subscribers who have been their patients. If any body of physicians is inclined to disagree on this point, we should welcome their indicating wherein we are wrong and how the public can be given this service more conservatively. In this connection we have entertained the apprehensions expressed by Dr Fitz in his letter published in the January 11 issue of the *Journal* and we heartily approve his recommendation.

Finally those of us who are attempting to render a public service are concerned with the freedom permitted individual physicians in determining whether they wish or do not wish to co-operate in making available to the public such a voluntary plan of budgeting medical costs. As can be plainly seen, the freedom accorded physicians in this matter is not the concern only of a medical profession organized on and believing in democratic principles, but also of the public.

I trust that such differences in viewpoint and opinion may arise in the course of providing this service may be discussed fully and adequately by all whose interests are involved so that the action finally taken at each stage in our progress will help solve, not add to, the problems before us.

FRANCIS H. RUSSELL, *President*
Health Service Incorporated

18 Tremont Street,
Boston

REPORTS OF MEETINGS

GREATER BOSTON MEDICAL SOCIETY

At a regular meeting of the Greater Boston Medical Society at the Beth Israel Hospital on November 7, 1939 Dr Max Rutov introduced the speaker Dr Morris Fishl

bein, editor of the *Journal of the American Medical Association*. Dr Ritvo gave a brief biography of Dr Fishbein, from his birth in Missouri in 1889, through his education at Rush Medical School from 1910 to 1912, his position as assistant editor of the *Journal of the American Medical Association* from 1913 to 1924, and his tenure as editor from the latter date to the present. He also indicated the tremendous amount of work entailed in the life of a man who not only has positions on two medical school faculties, but also has published fifteen books and conducts a daily health column appearing in two hundred newspapers.

The title of the evening's talk was "The Medical Profession and the American Government." The speaker maintained that such a subject would not now be under discussion had either party concerned itself with the other in 1918. That was not the first agitation for so-called social medicine, however, for the House of Delegates of the American Medical Association had recommended as early as 1876 the carrying out of the proposal of Dr Bowditch, of Boston, for a national health council and national secretary of health. Dr Fishbein, in reminding his audience that such a plan had not as yet been realized, stated that such a condition would persist until the medical profession made an agitation such as that now being carried out by the government.

In 1913-14, the first modern enthusiasm for compulsory sickness insurance followed the enactment of such a law in Great Britain through the efforts of Lloyd George. Since that time a small group of people, who have since worked "persistently, relentlessly and ruthlessly," have tried to develop federal legislation for medical care. Their associations at that time were with philanthropic organizations, but they are now found on essentially all governmental welfare and health committees.

In 1932 the Committee on the Costs of Medical Care suggested a program which would find the entire medical profession reorganized around the hospitals, with employed doctors as specialists and the local physicians as "feeders." The patients were to be organized voluntarily, and there was to be a non medical administrative agency in each state to carry out the distribution of doctors, organization of patients and so forth. Dr Fishbein at that time condemned the proposal as revolutionary rather than evolutionary and compatible with socialism if not communism.

The proposed enactment of the Social Security Law in 1933 led to the appointment of a technical advisory committee for medicine, headed by the ubiquitous non medical economists aforementioned. The American Medical Association became aroused when compulsory sickness insurance was tentatively suggested. The subsequent conclave of the House of Delegates led to President Roosevelt's summoning twelve doctors, headed by the late Harvey Cushing, to a conference. Dr Fishbein was particularly hearty in his praise of Dr Cushing's endeavors, which so resulted that compulsory sickness insurance was deleted from the bill. There was, however, \$10,000,000 appropriated for use by the United States Public Health Service and the Department of Child and Maternal Welfare. Dr Fishbein stated that some states have an increasing residue of this jointly raised money because of the lack of adequately trained men and projects on which to spend this appropriation. A similar condition obtaining in the fields of genitoinfectious diseases, cancer and poliomyelitis led the speaker to suggest that, at present, money is far from the sole answer to existing medical ills.

As to the practicality of assessing each worker 4 per cent of his salary for sickness insurance, Dr Fishbein pointed out that an additional 300,000 government em-

ployees would be necessary to carry out the clerical work alone. And to show that the present Social Security system of collection and distribution is still experimental, it was stated that there are now 12,000,000 "John Doe" cards in Washington, that is, cards whose owners are unknown to the government.

More recently 4000 WPA workers were employed in a national health survey which resulted in the National Health Program. In order ostensibly to draw up the provisions of this program, the National Health Conference was called. Dr Fishbein stated that a reliable high official admitted after the meeting that the conference was "stacked against the medical profession." Eighty per cent of the delegates were known to be in favor while, Dr Fishbein claimed, fully 95 per cent of even the audience were selected for their known propensities. The speaker alleged that Mr Harry Hopkins had the complete program in hand eight months before the conference but that no physician saw its provisions before the second day of the conclave. Naturally, the program remained intact but without the necessary legislative backing as yet. In presenting the proposal to the Senate, President Roosevelt "wisely" suggested careful study of its provisions and refrained from recommending its enactment.

The prospective emergency led to another special meeting of the House of Delegates of the American Medical Association. This was dominated, according to Dr Fishbein, by a group of public-health officers who were desirous of procuring control of the care of the indigent and medically indigent.

Attempts by many medical committees to modify the National Health Program failed, even though they financed their own expenditures to Washington. The proponents of the program, however, were not content to allow the proposals to simmer in a committee and sought the aid of Senator Wagner, of New York, who is rightly proud of his record in social legislation. He, together with the ever-present non medical opportunists and some newly recruited medical colleagues, collaborated on the Wagner Health Bill.

In regard to the opposition by the American Medical Association of certain group health organizations, the speaker stated that there were only a few of four hundred such groups condemned. The reasons for such action lay in their attempts to bid for patients, their undercutting of fees and their promise to provide more than they could possibly give. It was this last criticism which was particularly stressed, since so few lay people are cognizant of what constitute necessary and adequate procedures.

As to the immediate future, Dr Fishbein stated that either a modified Wagner Bill or an entirely new plan of similar nature would be an administration measure in the next campaign, regardless of the victorious party. And during the respite given the American Medical Association by the Supreme Court's denial for a governmental appeal, Dr Fishbein promised that the Association would offer suggestions for the appropriation of federal money for those communities where there was actual need. For there are many localities in what the speaker called "the foremost country in medical service" where no aid is necessary under present conditions. It was offered as evidence of the good faith of the profession that it annually contributes \$365,000,000 for medical service, compared with a total expenditure by the government, with the exception of the Army and Navy, of \$120,000,000. Dr Fishbein did not deny the necessity of some improvements despite this generally adequate medical service, but claimed that an emergency did not exist and that the profession itself was entirely capable of solving its own

problem. One third of the nation is not, alleged the speaker without medical care. For although over 40 per cent of the populace have an income of less than \$1500 per annum 48 per cent of the population lives in rural areas and needs neither the same income nor as much for medical care as does its urban counterpart.

In conclusion Dr Fishbein maintained that the American Medical Association does not oppose the distribution of the cost of medical care so long as the integrity of the individual is maintained. He mentioned that true but appropriate quotation "He who barter liberty for security is likely to lose both"

HARVARD MEDICAL SOCIETY

A regular meeting of the Harvard Medical Society with Dr. Soma Weiss presiding was held on November 14 1939 at the Peter Bent Brigham Hospital.

The first case presented was that of a fifteen-year-old girl who entered the hospital acutely ill with delirium a temperature of 104 F., and a painful swollen knee. Diagnoses of pyogenic arthritis, osteomyelitis and septicemia were made. Dr. William T. Green, in discussing the case, emphasized the importance of the care of the patient rather than an active surgical attack on the local disease in the early stages of a suspected osteomyelitis. Thus, the patient was treated with parenteral fluids, transfusions, sulfapyridine, immobilization of the affected limb and marsupialization of the suppurative knee joint. Early drainage and guarded motion of the joint were considered permissible whereas surgical intervention for the osteomyelitis in the contiguous femur was postponed until the patient's condition would warrant it. Dr. Green said that from the x-ray appearance of the bone lesion the joint infection was probably secondary to that focus. It was stated that the only way in which early drainage of osteomyelitis prevented subsequent complications was by its high mortality. In summarizing the treatment of staphylococcal septicemia, Dr. Green stated that multiple small transfusions and sulfapyridine offered the most promising results at present.

Dr. Chester S. Keefer was of the opinion that sulfapyridine was far superior to sulfanilamide in such cases. He mentioned the limited experience of Spink who had eight cures in 12 proved cases of staphylococcal septicemia as compared with the usual mortality of 80 to 85 per cent. In discussing the primary focus for the suppurative arthritis, Dr. Keefer stated that any staphylococcal joint infection without evidence of an external wound was invariably secondary to a contiguous osteomyelitis which had perforated the capsule.

The second case was that of a sixty-seven-year-old man who had entered the Peter Bent Brigham Hospital seven weeks before with a swinging temperature, night sweats, anorexia, weight loss and an exacerbation of his heart disease. In 1937 he had had a sudden attack of pulmonary edema and other signs of decompensated heart disease after eleven years of hypertension and a loud systolic murmur was heard for the first time. There was no history of rheumatic fever or congenital heart disease. In the intervening two years there had been intermittent attacks of decompensation successfully treated with digitalis, diuretics, barbiturates and paracentesis. The urine showed an increasing number of red blood cells, there were skin petechiae, and blood cultures showed profuse growth of *Streptococcus viridans*. Treatment consisted of sulfapyridine, which caused a marked temporary remission, and was then replaced by sulfanilamide, with an equally good temporary effect. Continuous intravenous heparin was employed until financial reasons caused its

discontinuance. Resumption of sulfanilamide following a respite caused an exacerbation rather than improvement.

Dr. Samuel A. Levine discussed the unusual case, which presented the unique features of an onset of subacute bacterial endocarditis during known congestive heart failure and of no predisposing cause such as rheumatic or congenital valvular disease. He did not believe that the therapeutic regimen carried out offered much promise.

The speaker of the evening was Dr. Chester S. Keefer whose subject was "Hemolytic *Streptococcus* Infections: Their importance in acute and chronic diseases." This was a résumé of some observations made by the speaker and his collaborators at the Thorndike Memorial Laboratory during the past six years. The toxic as well as invasive properties of *Streptococcus hemolyticus* were discussed together with its propensity for acute or chronic suppurative complications following a latent period. Dr. Keefer briefly mentioned the nine recently determined serological groups, with only Group A being significant for man clinically. The differentiation of at least 25 specific types within Group A has been accomplished by serological tests. Of 1150 strains of hemolytic streptococci studied at the Boston City Hospital from all available cases 95 per cent fell in Group A while only about 2 per cent belonged to each of Groups B and C. The Group B strains were usually found in cases of puerperal sepsis and those of Group C in wound sepsis, particularly in patients with diabetes. Last year at the Boston City Hospital 75 per cent of the scarlet fever streptococci were typable and showed a predominance of Types 13 15 16 and 17.

Dr. Keefer then went on to discuss the various phases of streptococcal infections their clinical manifestations and prognosis. The arbitrary divisions were a toxic phase, represented by the eruption of scarlet fever a septic phase, such as a lymphangitis and cellulitis a latent phase of ten days to six weeks, without symptoms a phase of late non-suppurative manifestations and finally overwhelming septicemia. The reason for the localization in certain cases was attributed to a bacterium which was noninvasive or of low virulence or to an increased resistance of the host as the result of specific antibodies. The importance of the local inflammatory fixation, even in the presence of circulating antibodies, was stressed.

The complex mechanism of recovery was examined, and its puzzling contradictions discussed. In most cases with a favorable outcome a co-operative activity of both local resistance and specific antibodies could be demonstrated. Some patients, however were known to recover without demonstrable antibacterial antibodies although they might have circulating antitoxin against the streptococcal products. Furthermore, the antibody titer was usually elevated for from one to six months after recovery even in those cases with exacerbations. Generally however an increase in demonstrable antibodies was shown to favor recovery.

Dr. Keefer's next consideration was the stage of septicemia, in which the use of chemotherapy had markedly reduced the mortality from its former value of 75 per cent. Three peaks of incidence were described, that of the first decade resulting from nose and throat foci that in the third and fourth decades being attributable largely to puerperal sepsis and that of later life complicating cellulitis. The course was variable there were cases of fulminating sepsis with death in three to five days and with no demonstrable antibodies there were patients who sterilized their blood stream and never developed metastatic lesions a third group had temporary clearing of the blood with later metastases, where the eventual outcome de-

pending on whether these secondary foci could be drained adequately, and finally there was the group who develop secondary bacteremia and die in two to three weeks. Emphasis was laid on the fact that focalized infection indicates the presence of adequate antibodies.

Discussion of the controversial mechanism of the late nonsuppurative manifestations of hemolytic streptococcus infections consumed much time and attention. The hypothesis of Pirquet and Schick that the reaction results from any antigen-antibody reaction must explain away the presence of this situation in all convalescent patients. Dr. Keefer suggested that those who fail to demonstrate these complications destroy their antigen before sufficient antibody titer is built up. Although such a mechanism might explain the latent period, it failed to elucidate the reason for the characteristic distribution of the lesions. Drs. Keefer and Mallory attempted to evaluate the presence of reactions in the tissues. It was found that those who succumbed early showed numerous bacteria in the interstitial tissues of the various organs and no reaction about them. In those dying on the sixth to the tenth day, however, bacteria were absent from the tissues, and a leukocytic reaction was present in areas corresponding to those previously invaded by streptococci. It was concluded that antigen was early disseminated throughout the tissues and fixed, while the later accumulation of antibodies caused a progressive tissue reaction. It was believed that this latter phenomenon was probably the same in the survivors.

Dr. James P. O'Hare opened the discussion by asking if such a theory was not in accord with Councilman's "acute interstitial nephritis." Dr. Keefer said that the lesions were identical with those described and pictured by Councilman. He did not agree, however, that acute interstitial nephritis never causes renal insufficiency.

Dr. Levine asked whether the late nonsuppurative manifestations were possible where no antibodies were demonstrated after a few days. Dr. Keefer agreed that Coburn's work seemed to indicate that a sharp antibody response was more prone to lead to recrudescences and said that the same had been found true by his co-workers.

Dr. Champ Lyons reported that specific antibodies were much more infrequently demonstrated in surgical streptococcal infections and that local inflammatory fixation probably plays a far more important role in such instances. Dr. Keefer agreed that there was a wide quantitative variance between the extreme medical and surgical cases, but emphasized the pressing need, therefore, for great caution in maintaining an intact local barrier in the necessary surgical treatment of such cases.

NOTICES

LECTURES AT THE FAULKNER HOSPITAL

A series of illustrated, public, health lectures at the Faulkner Hospital will be held in the hospital auditorium at 4:00 p.m. on Sundays. The schedule is as follows:

January 28—Diseases of the Rectum. Dr. Franklin G. Balch, Jr.

February 4—Heart Disease. Dr. Burton E. Hamilton.
February 11—Cancer of the Stomach. Dr. Marshall K. Bartlett.

February 18—Hay Fever and Asthma. Dr. Walter S. Burrage.

February 25—Surgery of the Blood. Dr. E. Everett O'Neil.

March 3—Surgical Diseases of Bone. Dr. John D. Adams.

March 10—New Drugs for the Treatment of Infectious Diseases. Dr. W. Richard Ohler.

March 17—Doctor, Will My Baby Be Normal? Dr. Charles P. Sheldon.

March 31—Eczema in Babies. Dr. Lewis W. Hill.

PETER BENT BRIGHAM HOSPITAL

A joint medical and surgical clinic at the Peter Bent Brigham Hospital will be held on Wednesday, January 31, from 2 to 4 p.m. Drs. Soma Weiss and Elliott C. Cutler will speak on "Obesity." A clinicopathological conference conducted by Dr. Elliott C. Cutler will take place from 4 to 5 p.m.

On Thursday, February 1, from 8:30 to 9:30 a.m., there will be at the Children's Hospital, a combined clinic, conducted by Dr. Frank R. Ober, of the medical, surgical, orthopedic, and pediatric services of the Children's Hospital and the Peter Bent Brigham Hospital.

Physicians and students are cordially invited to attend.

FAULKNER HOSPITAL CLINICOPATHOLOGICAL CONFERENCE

The monthly clinicopathological conference of the Faulkner Hospital will be held on Thursday, February 1, at 5:00 p.m. There will be a discussion of cases by Dr. Thomas J. Anglem and Howard B. Jackson.

Interested members of the medical profession are invited to attend.

GREATER BOSTON MEDICAL SOCIETY

A meeting of the Greater Boston Medical Society will be held in the auditorium of the Beth Israel Hospital on Tuesday evening, February 6, at 8:15.

Clinical papers will be presented by members of the staff of the New England Medical Center: Dr. Ethan L. Brown, Dr. Herbert I. Harris, Dr. Samuel Proger, Dr. William M. Shedden and Dr. S. J. Thannhauser.

MAX RITVO, M.D., *President*

DAVID B. STEARNS, M.D., *Secretary*

NEW ENGLAND HOSPITAL FOR WOMEN AND CHILDREN

The monthly clinical conference and meeting of the staff of the New England Hospital for Women and Children will be held at the hospital on Thursday, February 1, at 7:15 p.m.

NEW ENGLAND PEDIATRIC SOCIETY

The next meeting of the New England Pediatric Society will take place on Wednesday, February 7. The clinical meeting will be held in the amphitheater of the Children's Hospital, and all the other events at Longwood Towers, Brookline.

WACHUSETT MEDICAL IMPROVEMENT SOCIETY

There will be a dinner and meeting of the Wachuset Medical Improvement Society at the Bancroft Hotel in Worcester on Wednesday, February 7, at 6:30 p.m. Dr. Edward J. O'Brien, Jr., of Boston, will speak on "Surgical Treatment of Prostatic Obstruction." Dinner will be \$1.25 per plate.

Members of the profession are cordially invited to attend.

LEROY E. MAYO, M.D., *Secretary*

PROGRAM

- 4:00 Clinical meeting
5:30 "Refreshments."
7:00 Dinner
8:00 Business meeting

Symposium Treatment of Meningitis.

- Treatment of Epidemic and Streptococcal Meningitis. Dr Josephine B. Neal, New York City
Treatment of Pneumococcal Meningitis. Dr Maxwell Finland.
Treatment of Influenzal Meningitis. Dr LeRoy Fothergill.
Discussion. Dr Kenneth D Blackfan.

Physicians are cordially invited to attend the clinical meeting and the symposium.

R. CANNON ELEY M.D., *President*
JAMES M. BATT M.D., *Secretary*

CONSULTATION CLINICS FOR CRIPPLED CHILDREN IN MASSACHUSETTS UNDER THE PROVISIONS OF THE SOCIAL SECURITY ACT

| CLINIC | DATE | ORTHOPEDIC CONSULTANT |
|-------------|-------------|-----------------------|
| Lowell | February 2 | Albert H. Brewster |
| Salem | February 5 | Harold C. Bean |
| Haverhill | February 7 | William T. Green |
| Brookton | February 8 | George W. Van Gorder |
| Gardner | February 13 | Mark H. Rogers |
| Worcester | February 16 | John W. O'Meara |
| Pittsfield | February 19 | Francis A. Slowick |
| Northampton | February 21 | Garry deN Hough, Jr |
| Fall River | February 26 | Eugene A. McCarthy |
| Hyannis | February 27 | Paul L. Norton |

UNITED STATES MARINE HOSPITAL

The staff meeting of the United States Marine Hospital, Chelsea, will be held at "The Hut," on Friday after noon, February 2, at 4:00. Dr J Dellinger Barney will talk, his subject being "More Progress in the Management of Urinary Calculi."

JOHN W. TRASK, *Medical Director in Charge*

SOCIETY MEETINGS AND CONFERENCES

CALENDAR OF BOSTON DISTRICT FOR THE WEEK BEGINNING SUNDAY JANUARY 28

SUNDAY JANUARY 28

- 4 p.m. Care of the Complexion. Dr. Perry C. Balrd, Jr. Free public lecture. Harvard Medical School, amphitheater of Building D.
4 p.m. Diseases of the Rectum. Dr. Franklin O. Balch, Jr. Illustrated, public, health lecture. F. Inner Hospital auditorium.
MONDAY JANUARY 29
12:15-1:15 p.m. Clinicopathological conference. Dr. S. Bert Wolfbach, Peter Bent Brigham Hospital amphitheater.
8:15 p.m. New England Heart Association. Beth Israel Hospital.
TUESDAY JANUARY 30
10-10 a.m. Anurysm and Rupture of the Ventricle of the Heart. Dr. W. N. Fulton. Joseph H. Pratt Diagnostic Hospital.
10 a.m.-12:30 p.m. Boston Dispensary tumor clinic.
12:15-1:15 p.m. X-ray conference. Dr. Merrill C. Soeman. Peter Bent Brigham Hospital amphitheater.
5 p.m. Hospital Research Council. Massachusetts General Hospital, Elber Dome.
WEDNESDAY JANUARY 31
12 p.m. Clinicopathological conference. Children's Hospital amphitheater.
2-4 p.m. Joint medical and surgical clinic. Peter Bent Brigham Hospital.
THURSDAY FEBRUARY 1
8:30-9:30 a.m. Combined clinic of the medical, surgical, orthopedic and pediatric services of the Children's Hospital and the Peter Bent Brigham Hospital, at the Children's Hospital.

*5 p.m. Clinicopathological Conference. Faulkner Hospital.

7:15 p.m. Monthly clinical conference and meeting of staff. New England Hospital for Women and Children.

FRIDAY FEBRUARY 2

- 10 a.m.-12:30 p.m. Boston Dispensary tumor clinic.
12 m. Urological conference at the Massachusetts General Hospital lower amphitheater. Out Patient Department.
12 m. Clinical meeting of the Children's Medical Service, Massachusetts General Hospital. Elber Dome.

SATURDAY FEBRUARY 3

10 a.m.-12 m. Medical staff rounds of the Peter Bent Brigham Hospital. Conducted by Dr. Samuel Weiss.

*Open to the medical profession.

JANUARY 26—Arlington and Belmont medical clubs. Page 122, issue of J. MAY 15.

JANUARY 27—Massachusetts Public Health Association. Page 122, issue of FEBRUARY 15.

JANUARY 28—Free public lecture. Harvard Medical School. Page 1042, issue of December 28.

JANUARY 28—Salem Hospital public lecture. Page 1042, issue of December 28.

JANUARY 28—Free public lecture. Quincy City Hospital. Page 77, issue of JANUARY 11.

JANUARY 28—March 31—Illustrated, public, health lectures. Faulkner Hospital. Page 164.

JANUARY 29—New England Heart Association. Page 122, issue of JANUARY 15.

JANUARY 30—Massachusetts General Hospital. Page 122, issue of JANUARY 15.

JANUARY 31—Joint medical and surgical clinic. Peter Bent Brigham Hospital. Page 164.

FEBRUARY 1—Combined clinic of the medical, surgical, orthopedic and pediatric services of the Children's Hospital and the Peter Bent Brigham Hospital. Page 164.

FEBRUARY 1—Monthly clinical conference and meeting of staff. New England Hospital for Women and Children. Page 164.

FEBRUARY 1—Clinicopathological conference. Faulkner Hospital. Page 164.

FEBRUARY 2—Staff meeting. United States Marine Hospital. Notice above.

FEBRUARY 3—Cancer of the Stomach. Dr. George Pack. Joseph H. Pratt Diagnostic Hospital. Page 122, issue of January 15.

FEBRUARY 6—Greater Boston Medical Society. Page 164.

FEBRUARY 7—New England Pediatric Society. Page 164.

FEBRUARY 7—Wachusett Medical Improvement Society. Page 164.

BOOK REVIEWS

Cardiovascular Diseases Their diagnosis and treatment. David Scherf and Linn J Boyd. 458 pp St. Louis. The C V Mosby Co, 1939 \$6.25

For the physician looking for a practical course in heart disease this book is as good as a trip to Vienna before the *Anschluss*. Indeed, much of the material might have been prepared from the lecture notes of the senior author, a distinguished Viennese cardiologist and teacher, now an émigré.

As thoroughly practical in its outlook as a bedside clinic, attention is constantly focused on the problem of the sick patient without the meticulous regard for classification so dear to the hearts of most textbook writers. The didactic method of presentation with no references makes for easy reading, although detracting from its value to the advanced student. It is rich with keen clinical observations and flavored with countless interesting therapeutic suggestions—not all of which will suit the fancy of Americans, who, ever since the days of Osler, have been skeptical about the effectiveness of drugs. Doubtless many a reader's eyebrow will rise at the recommendation of leeches to the thighs in coronary thrombosis for the prevention of venous thrombosis, locally for the treatment of thrombophlebitis and over the liver in acute hepatic engorgement.

The almost complete lack of illustrations is a pity, but the omission of electrocardiography from a book intended for practicing physicians is highly commendable. The authors state in their preface "Experience has shown that abbreviated discussions of electrocardiography serve mainly to confuse rather than aid the general reader." The book is of particular importance because in its approach to the subject it marks a distinct break from the British school, in which most of our native cardiologists have been nurtured.

Getting Ready to be a Father Hazel Corbin 48 pp New York The Macmillan Co, 1939 \$1.25

As its title intimates, this little book aims to instruct the prospective father as to his part in getting ready for the baby's arrival. To the man who does know something about it the approach will doubtless seem elementary. It really is, yet in many cases the most elementary instruction is what is most needed. The book may help some to feel that they are not quite useless encumbrances at the time of the blessed event, and that is something. Although simple, that which is said is perfectly sound.

Anatomy and Physiology Frederic T Jung, Anna R Benjamin and Elizabeth C Earle. 637 pp Philadelphia F A Davis Co, 1939 \$3.50

This book may be recommended as a textbook for study by nurses. In the presentation of the subject matter, the authors keep strictly to a middle course between brevity and fullness. Many four-color illustrations enhance the usefulness of the book. The paper is of good quality, and the diagrams and figures are well reproduced. A special feature of the text is the use of "correlative applications" at the end of the discussion of each topic.

THE BONE LESIONS ACCOMPANYING CERVICAL SPINAL-CORD INJURIES*

An End Result Study of 76 Cases

DONALD MUNRO, M.D.,† and WALTER WEGNER, M.D.‡

BOSTON

A CASUAL review of the literature on "broken necks" emphasizes the confusion that exists as to the therapy and ultimate prognosis of this traditionally dangerous injury. As one's experience increases, one's pessimism grows less, however, and at the same time systematic segregation of the various elements involved becomes more and more imperative.

The therapy and prognosis of injuries of the cervical spine that do not involve the cord are quite different from those in cases in which cord injury plays a part. Such a study as that by Roberts' loses much of its potential usefulness because of his failure to take this into consideration. It is also essential, in our opinion, to differentiate the true acute cord injury which occurs at the time of the accident and the chronic lesion in which the damage to the cord takes place later. The latter may be a proper subject for fusion, as advocated by Cone and Turner. Nevertheless, success with these late cases does not, as these authors imply, justify the use of the same therapeutic procedure in acute cases, even though the original bone injury may have been the same. Furthermore, it is futile to use for cervical spine and cervical-cord injuries the methods of treatment that may be applied properly to analogous thoracic or lumbar lesions. Finally adequate length of follow up must be included as an essential part of the evaluation of the efficiency of any therapy. For these reasons we propose to discuss only cervical injuries, only those that are truly acute, only those in which there has been both bone and spinal-cord damage, and only the diagnostic therapeutic and prognostic aspects of the bone lesion.

Our series is made up of 76 cases. In 34 of them the patients died in the hospital in twenty four

hours to two years after admission, a mortality of 45 per cent. Thirty-eight patients were discharged from the hospital with varying degrees of recovery, and 4 are still under treatment.

GENERAL CONSIDERATIONS

As our experience has increased certain fundamentals have forced themselves upon our consciousness. None of them are new, and all have been mentioned by previous authors. Despite this however we are convinced that their importance is not generally recognized and that further discussion of them will be profitable.

The commonest and perhaps the least understood of these principles have to do with the mechanism of cervical dislocations. They are most apt to occur between the first and second and between the fourth, fifth and sixth vertebrae. The atlanto-axial dislocations occur because the articular facets of the axis and atlas are horizontal or nearly so, and therefore the maintenance of the position of one of these vertebrae on the other depends only on the integrity of the ligaments and odontoid process. Although the articular facets are more nearly vertical in the inferior part of the cervical spine, the usual site for dislocations is between the lower vertebrae.

Nearly all cervical spine injuries occur as the result of indirect violence which causes excessive flexion. The flexion occurs partly as the result of a protective reflex and partly because of the structure of the spine. The latter consists essentially of two parallel columns, one in front of the other. The anterior column is made up of the vertebral bodies and the intervertebral disks, and the posterior column of the neural arches. These include the pedicles, articular pillars, laminae and spinous processes. The anterior column is compressible, because of the elasticity of the intervertebral disks, but the posterior column is rela-

*Read at the annual meeting of the New England Surgical Society, 5 km. Massachusetts, September 29, 1939.

‡Assistant in neurological surgery, Harvard Medical School; associate surgeon for neurosurgery, Boston City Hospital.

tively rigid. Linear stress applied indirectly to the spine through a blow on top of the head causes compression of the anterior column, while the posterior column maintains its length but bends forward to accommodate itself to the shorter anterior column. As flexion increases, the linear force develops a forward component which produces a shearing stress on the articular facets (Fig 1). This shearing tends to produce dis-

duce the result shown in Figure 2, in which the bodies of the vertebrae are widely separated. We know from x-ray evidence that this does not occur

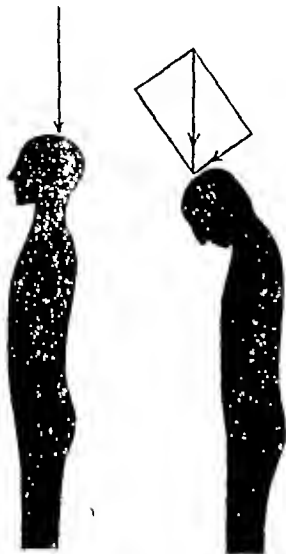

FIGURE 1

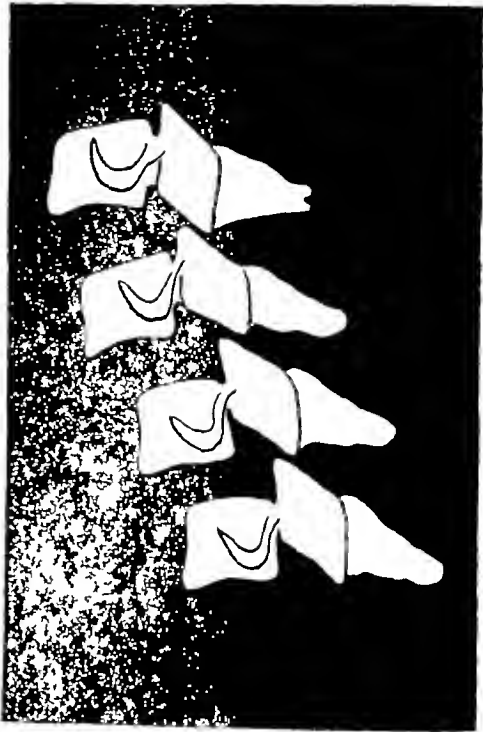

FIGURE 2

location, which is impeded by the oblique position of the facets and by the restraining ligaments and other fibrous structures, of which the intervertebral disks and the ligamentum flavum are the most important. The joint between the articular

when the uninjured neck is flexed, but rather that the anterior edges of the vertebral bodies come closer together (Fig 3). Such a motion is possible only if an additional tilting movement of the upper articular facet is exerted on the one below. Such tilting, if carried to excess, makes it

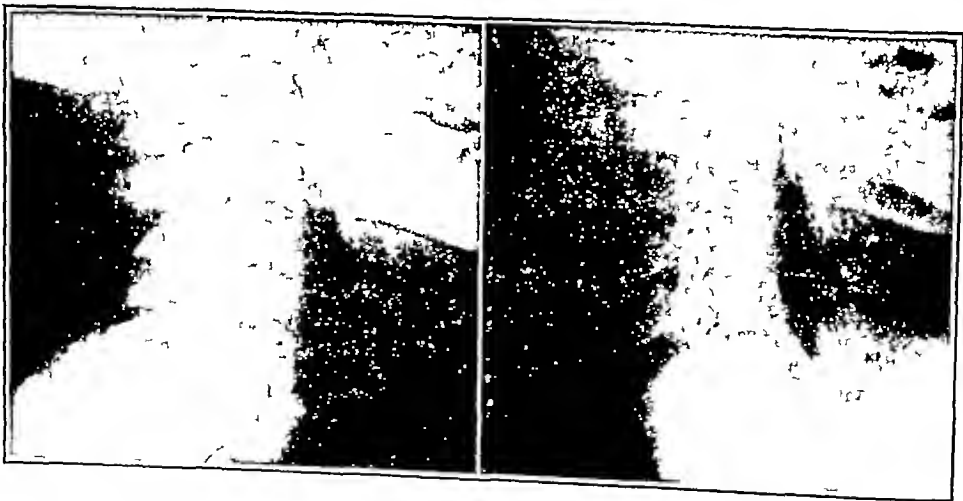

FIGURE 3

facets is enclosed in a loose capsule and has been described as arthrodial,⁵ which means that it has a gliding motion. If this were its only possible motion, however, an attempt at flexion would pro-

easy for the upper facet to override the lower, thus producing a dislocation without associated bone injury (Fig 4). Tearing of the intervertebral disk and the ligamentum flavum, however,

is apt to result. The stability of the neck following this type of injury is not augmented by such formation of callus as occurs when there has been extensive bone damage, and the dislocation is apt to recur if not fused. Regardless of type, we have

FIGURE 4

had only 7 cases of dislocation without associated fracture in the present series.

Any significant dislocation, and particularly the total variety of dislocation results in angulation of the vertebral canal (Fig 5). Thus, in turn, may cause pressure upon the cord at that point. It is nevertheless undoubtedly true that immediate partial to complete recoil of the partial dislocations may occur following the production of a degree

sionally supplemented by laminectomy and autopsy. Satisfactory visualization of the bone injury by x ray is difficult and often impossible. Attempts

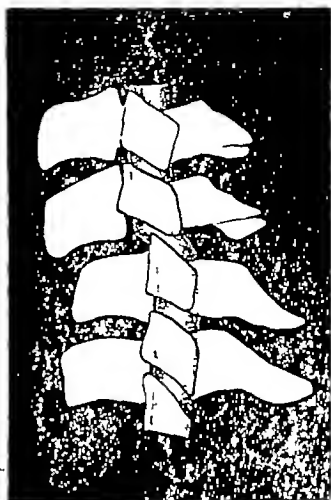

FIGURE 5

to take films should never be made unless the surgeon is present to see that flexion of the neck is avoided. Films should include lateral and antero-posterior views and a view through the open mouth. Cone and Turner have suggested that the base of

of cord injury that is inconsistent with the x ray findings at the time the patient is first seen.

Posterior dislocation of the cervical vertebrae is so rare as to be of no practical significance. It occurred only once in our series and was between the axis and the atlas. It followed a horizontal blow on the forehead and was accompanied by a fracture of the odontoid process.

DIAGNOSIS

The diagnosis of the bone injury (Table 1) has been made by x ray for the most part, being occa-

sionally supplemented by laminectomy and autopsy. Satisfactory visualization of the bone injury by x ray is difficult and often impossible. Attempts to take films should never be made unless the surgeon is present to see that flexion of the neck is avoided. Films should include lateral and antero-posterior views and a view through the open mouth. Cone and Turner have suggested that the base of the skull also be visualized. Traction on the shoulders may be required to show the sixth and seventh cervical vertebrae, and the roentgenologist should be given every assistance in his effort to obtain these difficult views. It is doubtless often impossible to show fractures of the articular facets even though oblique views are taken. We were able to visualize such a fracture only twice in this series.

TREATMENT

Treatment of the bone injury in this particular group of cases must be conditioned by the thera-

peutic needs of the damaged cord and the presence or absence of a spinal subarachnoid block. Since nearly all the injuries occurred in association with flexion, traction in hyperextension was usually provided at the start. The simplest, and we think the best, way of applying traction where only a moderate pull is needed is by a halter made of three-inch flannel bandage, as shown in Figure 6. This is led over a pulley at the head of

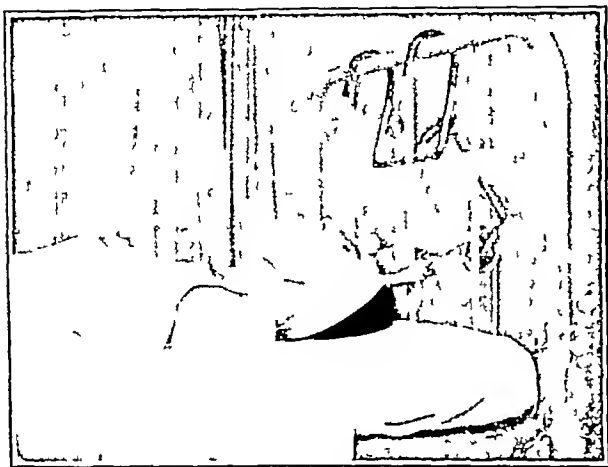

FIGURE 6

the bed and attached to a 5-pound weight. Flannel bandage is more comfortable and less apt to cause pressure sores around the chin and occiput than is the common leather halter. The chin is padded with lamb's wool, which does not become lumpy like cotton. The amount of traction that can be applied by this method is limited by the ability of the skin and the mandible to withstand pressure. Attempts to use more than a 5-pound weight have resulted in pressure sores of the chin and occiput, and in 1 case led to osteomyelitis of the mandible. Where greater amounts of pull were felt to be necessary, we have used Cone and Turner's² method (Fig 7). Traction is applied by a loop of rustless steel wire passed through two adjacent burr holes in the skull on either side of the midsagittal plane. A variation in the anteroposterior position of the burr holes alters the degree of hyperextension. Twenty-five or 30 pounds (in 1 case we used 60 pounds for twelve hours) can be suspended from such an arrangement for long periods of time, and with no discomfort to the patient. If necessary, a patient can even be set up in bed and the traction still be kept in place—a feature that is particularly useful for elderly people. Its disadvantages lie in the procedure necessary to apply it and in the occasional breaking of the wire or of the bone bridge between the trephine holes (each occurred in 1 case). Because of the handling necessary to apply it, this type of

traction was not used on acutely ill patients, and ordinarily not until after the first three days following injury. We have employed it in 7 cases.

Even with great weights, however, the method will not necessarily reduce a dislocation in which the facets are locked. This is particularly true if the direction of pull is in hyperextension. As Walton⁶ and subsequently Taylor⁷ pointed out, it is often well to begin traction in slight flexion, and to change to extension only after the facets have been so far separated as to permit the upper to slide backward into its proper position. This is especially true in complete dislocations, when the upper articular facets have become locked in front of the lower. We believe that it is safe to use Cone and Turner's method of reducing cervical dislocations even in the presence of associated fractures, and have done so.

We are opposed to the reduction of a dislocation by manipulation whenever there is an associated fracture of the laminae, pedicles or facets. Even with an ideal technic, such manipulations may cause unknown and uncontrolled shifts in the position of the fragments, with possible permanent damage to the cord. We have had occasion to use manipulation in 2 cases. One of the patients died a few hours afterward, and in the

FIGURE 7

other case the diagnosis was questionable. There was also 1 patient whose dislocation had been manipulated but not reduced before reaching us. He had no cord symptoms before the manipulation, but afterward there was quadriplegia with a complete block.

Even in the presence of a subarachnoid block and regardless of the bone damage, we no longer operate on cervical-cord injuries in the first few days after the accident. Although this change in policy happened to coincide with the introduction of tidal drainage⁸ and other improved methods of

handling these cases, it was probably the most important factor in reducing our mortality by 30 per cent (Table 2). However, if the subarach

TABLE 2. Influence of Laminectomy on Mortality Rate

| Total deaths | 19 | | 63 | | 15 | | 33 | |

noid block persists despite adequate traction and with or without reduction of the deformity, the cord is decompressed. In this connection it is worth while to note that we had 1 patient with a persistent spastic quadriplegia whose cord was not decompressed until ten days after the injury. A postoperative block developed, with subsequent symptoms suggestive of thrombotic transverse myelitis. This is in line with recent work on the circulation of the cord by Suh and Alexander⁹ and Herren and Alexander.¹⁰ The cord in the case noted appeared to be entirely normal and was not touched at operation. We believe that this may well represent the effect of allowing a block to go unrelieved for too long a period.

All our patients have been kept in traction for at least six weeks, and usually eight or nine. At the end of that time they are fitted with a leather cuirass having a high occiput but no forehead strap¹ or else, if there is x-ray evidence of sufficient bone repair and union to warrant it, a leather Thomas collar. Usually the patients have been allowed to remove the splint for the night after an other six weeks or two months. However, they have been made to wear it when upright and during the day until such time as there is x-ray evidence of solid bone union or repair at the site of the original fracture. They have been given no special exercises. We are opposed to the use of plaster-of-Paris jackets on account of their weight and discomfort, and the increased incidence of bed sores. We have never used one in an acute cervical-cord injury and the removal of several applied in other clinics has resulted in immediate improvement in the patients' condition. Moreover, 1 patient in this series came to us for treatment of a contusion of the cord with quadriplegia that had occurred during the application of a plaster cast. We believe that its use in cervical spine and cervical-cord injuries is dangerous and ordinarily contraindicated.

None of our cases have been fused. Excluding

5 patients who have been followed for less than six months, 2 who have been lost and 5 who are still in the hospital, we have 30 such patients who have been followed for one to fifteen years. Of these, 2 developed a recurrent late dislocation. In 1 case the dislocation was put back into correct position by skeletal traction, and there is reason to suppose that it will stay there. The other patient refused further treatment. Neither had any secondary cord symptoms. Contrary to Cone and Turner's² opinion, our experience has been that while, as they say, reduction is simple in the complex fracture-dislocations, under properly prolonged traction and splinting they are the least apt to slip and therefore the least in need of fusion. On the contrary,—and it was this condition that was present in our 2 cases in which slipping occurred,—dislocations without fracture are apt not to unite until late, because healing depends solely on ligamentous repair. They are prone to redislocate, and are therefore the cases *par excellence* for fusion.

Our experience with occipitodantlantoaxial and odontoid dislocations and injuries has been too small to justify any conclusions. Of our 2 patients—both with broken odontoid processes—one had an anterior and the other a posterior dislocation of the occiput and atlas on the axis. The anterior dislocation occurred in a chronically recurrent case with compression of the cord that eventually, after decompression, stabilized itself along the anterior aspect of the spinal column without any other fusion. The case with posterior dislocation is still on traction in the hospital.

All cord injuries regardless of the bone injury are placed on tidal drainage⁸ immediately after the patients' arrival on the ward. With the proper adjustment of the apparatus to the type of bladder it is serving, we have found it possible to do with our air, water, cork or other special mattresses. We believe Bradford frames to be distinctly harmful and unnecessary in the care of these cases. The patients can be turned more safely and come to less damage if kept on an ordinary mattress with the bed made up in the usual way and the drawsheet used to rotate them.

DISCUSSION

Age Distribution

The efficacy of any treatment that requires immobilization of the patient for six weeks or more may be materially affected by the age distribution of the group under consideration (Table 3). In this group of bone injuries associated with cervical-cord injuries, the effect of age on the efficacy of treatment was minimal and we do not believe

peutic needs of the damaged cord and the presence or absence of a spinal subarachnoid block. Since nearly all the injuries occurred in association with flexion, traction in hyperextension was usually provided at the start. The simplest, and we think the best, way of applying traction where only a moderate pull is needed is by a halter made of three-inch flannel bandage, as shown in Figure 6. This is led over a pulley at the head of

FIGURE 6

the bed and attached to a 5-pound weight. Flannel bandage is more comfortable and less apt to cause pressure sores around the chin and occiput than is the common leather halter. The chin is padded with lamb's wool, which does not become lumpy like cotton. The amount of traction that can be applied by this method is limited by the ability of the skin and the mandible to withstand pressure. Attempts to use more than a 5-pound weight have resulted in pressure sores of the chin and occiput, and in 1 case led to osteomyelitis of the mandible. Where greater amounts of pull were felt to be necessary, we have used Cone and Turner's² method (Fig 7). Traction is applied by a loop of rustless steel wire passed through two adjacent burr holes in the skull on either side of the midsagittal plane. A variation in the anteroposterior position of the burr holes alters the degree of hyperextension. Twenty-five or 30 pounds (in 1 case we used 60 pounds for twelve hours) can be suspended from such an arrangement for long periods of time, and with no discomfort to the patient. If necessary, a patient can even be set up in bed and the traction still be kept in place—a feature that is particularly useful for elderly people. Its disadvantages lie in the procedure necessary to apply it and in the occasional breaking of the wire or of the bone bridge between the trephine holes (each occurred in 1 case). Because of the handling necessary to apply it, this type of

traction was not used on acutely ill patients, and ordinarily not until after the first three days following injury. We have employed it in 7 cases.

Even with great weights, however, the method will not necessarily reduce a dislocation in which the facets are locked. This is particularly true if the direction of pull is in hyperextension. As Walton⁶ and subsequently Taylor⁷ pointed out, it is often well to begin traction in slight flexion, and to change to extension only after the facets have been so far separated as to permit the upper to slide backward into its proper position. This is especially true in complete dislocations, when the upper articular facets have become locked in front of the lower. We believe that it is safe to use Cone and Turner's method of reducing cervical dislocations even in the presence of associated fractures, and have done so.

We are opposed to the reduction of a dislocation by manipulation whenever there is an associated fracture of the laminae, pedicles or facets. Even with an ideal technic, such manipulations may cause unknown and uncontrolled shifts in the position of the fragments, with possible permanent damage to the cord. We have had occasion to use manipulation in 2 cases. One of the patients died a few hours afterward, and in the

FIGURE 7

other case the diagnosis was questionable. There was also 1 patient whose dislocation had been manipulated but not reduced before reaching us. He had no cord symptoms before the manipulation, but afterward there was quadriplegia with a complete block.

Even in the presence of a subarachnoid block and regardless of the bone damage, we no longer operate on cervical-cord injuries in the first few days after the accident. Although this change in policy happened to coincide with the introduction of tidal drainage⁸ and other improved methods of

that age need be considered a significant factor if treatment is carried out as outlined

Spinal-Cord Injury

Obviously the outcome of the bone injury, in terms of usefulness, will depend on the extent of

*In 4 cases block occurred without any other diagnosable cord injury

except in the case following manual reduction of the dislocation, we can say that the bone lesion is not a factor. The causes listed in Table 5 are symptomatic rather than etiologic.

End Results

As has been pointed out above, the end result of the bone injury itself has been fusion of a varying degree and with an approximation to normality except in 2 cases (Table 6). Crippling arthritis of the arms and hands, and less so of the legs, has prevented the attainment of the potentialities for recovery that have rested in the older patients. This has necessitated classification of some cases as having had an unsatisfactory end result. Those classed as satisfactory have been considered to be so by the patients themselves. They are able to care for themselves and get about freely, but not to earn a living. Those classed as well can earn their living in addition.

SUMMARY AND CONCLUSIONS

The therapy and prognosis of cervical-spine injuries which do not involve the spinal cord or are already chronic when first seen are quite different from those in which the cord injury plays a part and in which the patient comes for treatment immediately following the receipt of his injury.

Treatment of the bone injury in combined cervical-spine and spinal-cord injuries is condi-

other procedures, our mortality in cervical-cord injuries has dropped over 30 per cent since we have abandoned immediate laminectomy as a therapeutic measure.

In a series of 76 cases, 30 of which have been

literature, found not a single case of correct diagnosis

Since pain from ovulation and its concomitant phenomena is most frequently mistaken for appendicitis, we studied the relative incidence of the two conditions during two typical years at the hospital. In both 1935 and 1936 there were 39 cases of acute abdominal pain considered due exclusively to ovulation or to a ruptured corpus hemorrhagicum. In 1935 there were 556 cases and the following year 504 cases of appendicitis of all degrees occurring in women between the ages of thirteen and forty five, the age period when symptoms from ovulation occur. Thus in the latter class of hospital admissions there was an incidence of 1 case with pain from ovulation to every 13 of appendicitis.

In order to determine how frequently ovulation might cause discomfort in the abdomen, not severe enough to demand medical aid, we questioned for a month all gynecological patients who had normal menstrual regularity and found that 21 out of 134 patients, or about 1 in 6, frequently had abdominal pain of a minor degree midway between periods when ovulation would ordinarily occur. During this study we found that 53 of 134 patients (40 per cent) had some symptoms suggesting ovulation such as spotting, soreness of the breasts, leukorrhea or abdominal pain.

Our series, from 1926 through 1938, may be differentiated into three categories. First, there were 74 cases, including 15 which were discharged without operation, which could be considered as those of ruptured graafian follicles. The 59 operated cases in this group were characterized by an absence of free blood in the peritoneal cavity but by evidence of recent ovulation in the form of a distinct unruptured corpus hemorrhagicum. In this group nothing was done surgically to the ovaries. The unoperated cases showed mild symptoms which cleared up a few hours after entry.

Second, there were 165 cases of ruptured corpus hemorrhagicum, of which 139 were operated on. The operated cases showed evidence of free blood in the pelvis ranging from 1 to 120 cc. of sero-sanguineous fluid. The majority of these cases showed a small amount of blood and a ruptured corpus hemorrhagicum about 1 or 2 cm. in diameter. Of this latter group 39 patients were still oozing blood at the time of operation. All the corpus hemorrhagicum cases were treated by mattress suture.

In the third category there were 18 cases of corpus hemorrhagicum cyst, of which 13 had ruptured. Resection was done in all the cases of this group and the pathological diagnosis was corpus hemorrhagicum cyst or corpus luteum cyst with hemorrhage. Since we have not included any

cases with obvious signs of intra abdominal hemorrhage, so well described by other authors,¹⁻⁴ the cases in all three categories presented similar general symptomatology differing only in minor details.

The variable degree of discomfort caused by these conditions is shown by the fact that 30 per cent of the patients came to the hospital on the first day of their attack, 67 per cent within three days and the remaining 3 per cent anywhere from the fourth to the twenty-first day after the pain had started.

The difficulty in the management of many of these cases is well demonstrated by the fact that, of the 216 patients who were operated on, 58 were observed from three to nine days before operation was performed the other 158 were considered sick enough to justify operation on the day of entry or the next day. Those who were not operated on were kept in the hospital for two to four days before discharge.

The ages varied from ten to forty five years, with 73 per cent of the cases occurring between fifteen and twenty five. Single women comprised the larger part of the latter group. Many of the unoperated cases however, would tempt one to venture the opinion that single women had a lower threshold for pain than married women the latter being more liable to carry on through the discomfort without being hospitalized.

The time of onset in relation to the last menstrual period was determined in 162 cases. The pain started between the eighth and the twenty first day after the beginning of the last period. One hundred and thirteen, or 70 per cent, of these cases occurred between the twelfth and the sixteenth day after the onset of the last menses. The patients with ruptured graafian follicles invariably had their symptoms at the middle or in the early part of the intermenstrual interval. Many of the cases of ruptured corpus hemorrhagicum started at the middle of the cycle, but the majority occurred in the latter part. All the patients with corpus hemorrhagicum cysts had their symptoms about twenty-one days after the first day of the last period.

The pain was sharp and knifelike, at times radiating to the umbilicus but more often diffuse across the whole lower abdomen. In 12 cases there was pain in the back, and in 5 the pain radiated to the right knee. In the latter group more blood was usually found in the pelvis than is ordinarily encountered. The pain was distinctly intermittent, except in the cases with cysts, and tended after its acute onset to localize in the right lower quadrant of the abdomen even if the left ovary was involved. In our series there were 32 cases in which the left ovary was involved and

25 of these had right-sided pain. The pain seemed to subside considerably or completely in the recumbent position and was distinctly aggravated by exercise.

Trauma, such as that caused by walking, running, bending, coitus and getting out of bed, was elicited in 18 cases as a precipitating cause. This number would probably have been considerably larger had the patients been questioned more carefully regarding the relation of their attacks to some form of trauma, especially that of mild degree, which imperceptibly increases intra-abdominal pressure.

Our study would suggest that the cases with ruptured follicles had an acute onset, the acute stage lasting but a few hours, whereupon there followed a period, variable in length but usually brief, of discomfort in the lower abdomen. The cases of ruptured corpus hemorrhagicum after their acute onset were characterized by periodic alleviation of the pain, with acute exacerbations when the individual resumed activity. The symptoms in these cases tended to be intermittent but lasted a long time. The cases with more profuse bleeding were naturally severe, with the pain continuous rather than intermittent, and more closely simulated an acute abdominal emergency. The cases of corpus hemorrhagicum cyst seemed more gradual in onset, except in ruptured cases, and the pain was invariably steady without interruption. The cases of ruptured cyst were the most fulminating of all.

As regards gastrointestinal symptoms, vomiting was relatively infrequent, occurring in 73 cases, and was usually found only in the more fulminating cases. It came early in the attack and was never particularly distressing. Nausea was more frequently complained of and occurred in 155 cases. Anorexia was practically always a feature. The bowels as a rule were not affected. There were 12 cases of mild diarrhea occurring six to forty-eight hours after the onset of the attack, suggesting peritoneal irritation in the posterior cul-de-sac. Nothing very distinctive could be deduced from these data, but the vomiting had a tendency to be considerably less severe than that seen in the acute obstructive types of appendicitis, as suggested by Pratt⁶; on the other hand, it seemed to occur sooner after the pain than it did in the acute cases of appendicitis.

A history of previous attacks was elicited in 98 cases. In the ruptured follicle group, 39 patients (52 per cent) had had previous attacks, 31 having had several and 8 only one. In the ruptured corpus hemorrhagicum group, 52 patients (31 per cent) gave a history of previous similar trouble, 37 having had several attacks and 15 one. In the cyst

group, 7 patients (38 per cent) had had a similar previous disturbance, 4 having had several attacks and 3 one, the other attacks invariably occurred in the late part of the interval between periods. There were only 8 cases with a history of pain occurring at regular monthly or bi-monthly intervals, 6 of these being among the ruptured follicle cases which were not operated on.

Since the majority of such cases are confused with appendicitis, we were interested to see how many patients had had a previous appendectomy. In the entire series of 257 cases, only 6 patients had had their appendices removed. Of these, 1 case with pain on the left side and 2 cases with pain on the right side were diagnosed as ruptured corpus hemorrhagicum and the patients were discharged without operation. The other 3 were operated on, 1 case with left-sided pain being diagnosed as an ovarian cyst, and the other 2 with pain on the right side as adhesions and ectopic pregnancy, respectively.

The number of white blood cells varied from 4000 to 30,000. One hundred and sixty-four patients (64 per cent) had a count of 10,000 or less, 77 (30 per cent) had a count from 10,000 to 15,000, the rest (6 per cent) had counts ranging from 15,000 to 23,000. The white-cell count had a distinct tendency to fall in a short period of time or to stay elevated if there was much old blood in the pelvis.

The temperature varied from normal to 103°F, in most cases being about 99.6°F. In 30 cases (12 per cent) it was between 100 and 101°F. In 23 cases (9 per cent) it reached 103°F. The presence of old blood seemed to keep the temperature elevated.

The pulse varied but slightly from normal, and did not seem to rise commensurately with the temperature. Rarely was it above 100 beats per minute except in the few cases of ruptured hemorrhagic cyst, in which all the symptoms were more fulminating in type. After the initial onset the pulse tended to drop or remain stationary, in contradistinction to the patient with acute appendicitis, who tends to have a constantly rising pulse.

There was tenderness on deep pressure throughout the whole lower abdomen, particularly in the right lower quadrant, even if the lesion was on the left. Tenderness below McBurney's point was of considerable aid in differential diagnosis. Muscle spasm was conspicuous by its absence, as was rebound tenderness.

Vaginal or rectal examination, when done, usually showed slight tenderness in the affected vault, with occasional fullness in either fornix or the posterior cul-de-sac, depending on the amount

of blood present. The tenderness was distinctly low in the pelvis in the region of the involved ovary. Eight cases were considered to have a mass in one of the vaults and were diagnosed as cysts of the ovary.

The diagnoses made in the ruptured graafian follicle cases were as follows:

| | |
|----------------------------|-----------------|
| Ruptured graafian follicle | 15 (unoperated) |
| Acute appendicitis | 17 |
| Subacute appendicitis | 21 |
| Chronic appendicitis | 16 |
| Pelvic inflammation | 2 |
| Adhesions (postoperative) | 1 |
| Twisted ovarian cyst | 1 |
| Cyst of ovary | 1 |
| Total | 74 |

In the ruptured corpus hemorrhagicum series the following diagnoses were made:

| | |
|-------------------------------|--------------------|
| Ruptured corpus hemorrhagicum | 41 (26 unoperated) |
| Acute appendicitis | 55 |
| Subacute appendicitis | 47 |
| Chronic appendicitis | 12 |
| Ectopic pregnancy | 3 |
| Pelvic inflammation | 6 |
| Cyst of ovary | 1 |
| Total | 165 |

The cyst cases were diagnosed as follows:

| | |
|---------------------------------------|----|
| Ruptured corpus hemorrhagicum | 1 |
| Cyst of ovary | 4 |
| Acute appendicitis | 10 |
| Subacute appendicitis | 2 |
| No diagnosis (exploratory laparotomy) | 1 |
| Total | 18 |

From the foregoing data it is shown that the great majority of the cases in each group were confused with appendicitis—the milder forms in

Our study and the various articles written on acute abdominal symptoms following ovulation would seem to bring out certain features of distinct value in differential diagnosis. The important diagnostic points are:

History of previous similar attacks

Onset of pain within two weeks of due date of the next period.

Pain precipitated by mild trauma

Attack occurring in presence of other molar in a suggestive of ovulation, such as painful breasts, spotting and leukorrhea.

White-cell count at first elevated, tending to drop rapidly to normal

Tenderness 2 cm or more below McBurney's point.

Tenderness low in the pelvis by rectal or vaginal palpation

Omitting the cyst cases, both intact and ruptured, in which surgical intervention is invariably necessary we have charted (Table 1) the records of the Boston City Hospital showing the progress in the management of cases of ruptured graafian follicle and ruptured corpus hemorrhagicum, especially since publication of the excellent papers by Hoyt and Meigs⁷ and Wharton and Hendrickson⁸ in 1936. This chart demonstrates certain interesting facts. The ruptured graafian follicle cases have been reduced to zero presumably because these were recognized by the admitting surgeons and treated as outpatient cases. The increase in the average number of days the patients were observed before operation shows the more conservative handling of these cases.

The incidence of correct diagnoses increased, with a resulting decrease in surgical intervention. There still remained many cases in which surgi-

TABLE 1 Data Showing Advance in the Management of Cases

| Data | 1926-31 | 1931 | 1932 | 1933 | 1934 | 1935 | 1936 | 1937 | 1938 | TOTAL |
|---|---------|------|------|------|------|------|------|------|------|-------|
| Not diagnosed preoperatively | | | | | | | | | | |
| Graafian follicle | 4 | 10 | 21 | 9 | 8 | 4 | 2 | 1 | 0 | 59 |
| Corpus hemorrhagicum | 4 | 6 | 15 | 5 | 6 | 20 | 13 | 7 | 10 | 86 |
| Diagnosed but not operated on | | | | | | | | | | |
| Graafian follicle | 0 | 1 | 1 | 1 | 1 | 6 | 4 | 1 | 0 | 15 |
| Corpus hemorrhagicum | 0 | 1 | 2 | 1 | 1 | 1 | 4 | 5 | 11 | 26 |
| Diagnosed but operated on | 0 | 0 | 2 | 1 | 1 | 3 | 3 | 2 | 3 | 15 |
| Diagnosis considered but patient operated on | 3 | 2 | 2 | 1 | 0 | 5 | 13 | 5 | 7 | 38 |
| Totals | 11 | 20 | 43 | 18 | 17 | 39 | 39 | 21 | 31 | 239 |
| Incidence of correct diagnoses (per cent) | 0 | 10 | 11 | 16 | 16 | 23 | 28 | 38 | 45 | |
| Average days of observation before operation | 1.3 | 1.5 | 1.5 | 1.6 | 1.5 | 3 | 2 | 3 | 3 | |
| Incidence of surgical intervention (per cent) | 100 | 90 | 95 | 88 | 88 | 82 | 79 | 71 | 66 | |

the ruptured graafian follicle cases and the more acute forms in the ruptured corpus hemorrhagicum and ruptured corpus hemorrhagicum cyst cases.

cal intervention seemed necessary even though the diagnosis of ruptured corpus hemorrhagicum was made. In the latter group there was invariably found a corpus hemorrhagicum still oozing blood

at the time of operation. Although the percentage of correct diagnoses is increasing and is as high as that observed in other clinics, we believe that our results will be even better as the importance of this subject receives more prominence. Unquestionably there will always be a certain number of cases in which differentiation from appendicitis is impossible, but with histories carefully taken and examinations thoroughly made with these conditions in mind, the number of operative cases can be considerably reduced.

CASE REPORTS

CASE 1 (No 820505) L. S., a 25 year-old, married woman, was admitted to the hospital complaining of acute intermittent pain in the right lower quadrant of the abdomen of a few hours' duration. The last period had occurred 2 weeks previously. There had been no previous attacks of pain.

At examination the temperature was 98.6°F, the pulse 84, and the white cell count 9000. There was moderate tenderness in the right lower quadrant. There was no spasm and no rebound tenderness. Pelvic examination was negative.

A diagnosis of ruptured graafian follicle was made, and the patient was discharged in 2 days without operation.

CASE 2 (No 803835) J. W., an 18 year-old, unmarried woman, was admitted to the hospital with a chief complaint of acute, intermittent pain in the right lower quadrant of the abdomen, accompanied by vomiting and of several hours' duration. The last period had occurred 2 weeks previously. There had been no previous attacks.

At examination the temperature was 99.2°F, the pulse 96, and the white-cell count 10,000. There was definite tenderness in the right lower quadrant over McBurney's point. There was no spasm and no rebound tenderness. There was slight tenderness in the right side of the pelvis by rectal examination.

The diagnosis was thought to be either subacute appendicitis or ruptured corpus hemorrhagicum, but surgery was deemed advisable. At operation there was found a small amount of serous fluid and an unruptured corpus hemorrhagicum in the right ovary. The appendix was normal.

Comment Cases 1 and 2 illustrate, respectively, the mild and the more severe symptomatology which may be caused by rupture of a graafian follicle.

CASE 3 (No 813540) M. D., an 18 year old, unmarried woman, was admitted to the hospital complaining of acute pain in the right lower quadrant of the abdomen, radiating to the suprapubic region, of 6 hours' duration. Pain started during coitus. It was continuous and vomiting ensued shortly after onset. There was dizziness on standing and relief from the pain on lying down. The last period had occurred 26 days before onset.

Examination showed marked tenderness low in the right lower quadrant and over the symphysis. There was rebound tenderness and slight spasm. Vaginal examination showed marked pain on motion of the cervix. The right vault was tender, the left vault free, and no masses were felt.

At examination on admission at 4 a.m. the temperature was 98.6°F, the pulse 90, and the white-cell count 18,000. The white-cell count was 9000 at 9 p.m., and 8600 on the following day. An Aschheim-Zondek test was negative. The urine was negative.

The pain subsided on the day after admission, and the patient was discharged in 4 days with a diagnosis of ruptured corpus hemorrhagicum.

CASE 4 (No 897427) I. D., a 22-year-old, unmarried student nurse, was admitted to the hospital with a history of acute intermittent pain in the right lower quadrant of the abdomen of 24 hours' duration. The pain occurred directly over an old appendectomy scar. It did not radiate but became increasingly more frequent and severe. The patient vomited once and felt dizzy on two occasions. The last menses had begun 2 weeks before onset. For 4 years the patient had had dysmenorrhea and pain in the lower abdomen, lasting for 3 days to 2 weeks after her periods. An appendectomy had been performed 6 years previously.

On examination the patient was not acutely ill but complained of pain in the right lower quadrant of the abdomen. There was definite but not marked tenderness at the site of the old appendectomy scar. There was no spasm, mass or rebound tenderness. Slight radiation of tenderness was felt on palpation down to the middle of the symphysis. No rectal examination was made. The temperature was 98.6°F, the pulse 76, and the white-cell count 8500.

Surgical and gynecological consultants agreed on a diagnosis of ruptured corpus hemorrhagicum. The patient remained under observation for a week, during which time she had occasional slight pain on the affected side, and was then discharged without operation.

Comment Cases 3 and 4 are virtually textbook pictures of ruptured corpora hemorrhagica, the former demonstrating the value of repeated white counts, and the latter the importance of a good history.

CASE 5 (No C735366) T. P., a 17-year-old girl, was admitted to the hospital complaining of acute periodic pain in the left lower quadrant of the abdomen, radiating down the left leg, of 2 weeks' duration. There was no nausea or vomiting. The bowels were normal. The appetite was normal. There had been no previous attacks. The appendix had been removed 2 years previously. The last period had occurred 2 weeks before onset.

At examination the temperature was 99.8°F, the pulse 100, and the white-cell count 10,000. The urine was negative. There was tenderness in the left lower quadrant in the region of the left ovary. There was no spasm and no rebound tenderness. Rectal examination showed tenderness in the left vault.

A diagnosis of a ruptured corpus hemorrhagicum was made, and the patient was discharged in 3 days when the symptoms had subsided.

Comment This case shows symptoms persisting on the left side from which the ruptured corpus apparently came and also the ease with which these cases may be diagnosed if an appendectomy already has been performed.

CASE 6 (No 659307) M. O., a 14-year-old girl, was admitted to the hospital complaining of acute pain in the right lower quadrant of the abdomen, without radiation, of 3 days' duration. There was no nausea or vomiting. The appetite was poor. The bowels were normal. The last period had occurred 3 weeks before onset.

At examination the temperature was 99.6°F, the pulse 120 and the white-cell count 11,200. The urine was negative. There was tenderness in the whole right lower quadrant, without spasm. Tenderness was elicited high in the pelvis on rectal palpation.

A diagnosis of acute appendicitis was made and an operation was performed the day of entry. The appendix

was found to be normal and a ruptured corpus hemorrhagicum was found in the left ovary with a small amount of free blood in the pelvis.

Comment This case demonstrates that the symptoms from a rupture on the left side may occur on the right side.

Case 7 (No. 649622) E. A., an 18-year-old unmarried woman was admitted to the hospital complaining of acute pain in the right lower quadrant of the abdomen of 5 days duration. There was nausea but no vomiting. The bowels were normal. The last period had occurred 2 weeks before onset. The patient had had two similar attacks lasting for 4 days.

At examination the temperature was 99.4 F, the pulse 106, and the white-cell count 9000. There was tenderness over McBurney's point, but no spasm. Tenderness in the region of the cecum was shown by rectal examination.

A diagnosis of acute appendicitis was made and an operation was performed on the day of entry. An acutely inflamed appendix was found together with free blood in the peritoneal cavity and a ruptured corpus hemorrhagicum in the right ovary.

Comment This case illustrates the extreme difficulty in differential diagnosis and the possibility that acute appendicitis may be present simultaneously with a ruptured corpus hemorrhagicum.

Case 8 (No. 777355) V. S., a 15-year-old girl was admitted to the hospital with a chief complaint of acute intermittent pain in the right lower quadrant of the abdomen without radiation of 24 hours duration. There was nausea but no vomiting. The last period had occurred 2 weeks previously. The patient had had several attacks.

At examination the temperature was 98.6 F, the pulse 80 and the white-cell count 17,000. There was tenderness in the right lower quadrant over McBurney's point. There was no spasm and no rebound tenderness. The rectal examination was negative.

A diagnosis was made of acute appendicitis or ruptured corpus hemorrhagicum. At operation a ruptured corpus hemorrhagicum, still oozing blood was found in the right ovary. There was considerable blood-tinged fluid in the pelvis.

Comment Whether to intervene surgically in the above type of case would tax the judgment of even the most conservative surgeon.

Case 9 (No. 644132) C. L., a 15-year-old girl was admitted to the hospital with a chief complaint of dull pain in the right lower quadrant of the abdomen of 3 days duration. There was no nausea or vomiting. The pain became gradually worse. The last period had occurred 3 weeks before onset.

At examination the temperature was 99 F, the pulse 96, and the white-cell count 7000. There was deep tenderness with slight spasm in the right lower quadrant. There was tenderness in the right vault on rectal examination. No masses were felt.

A diagnosis of acute appendicitis was made and an operation performed on the day of entry. There was found about 5 cc. of bloody fluid in the right side of the pelvis. There was a hemorrhagic cyst of the right ovary unruptured and about the size of a walnut. Resection of the cyst was performed.

Comment This case illustrates the continuous dull pain characteristic of the cyst cases, in contradistinction to the intermittent pain caused by a bleeding corpus luteum.

Case 10 (No. 661313) M. O., a 28-year-old, unmarried woman was admitted to the hospital complaining of acute pain below the umbilicus, radiating to the right lower quadrant of the abdomen of 2 days duration. The patient had vomited four times. The pain was constant and was somewhat relieved by flexing the right thigh. The last menses had occurred 26 days previously.

At examination the temperature was 99 F, the pulse 110 and the white-cell count 12,000. There was tenderness and spasm in the right lower quadrant. Rectal examination showed tenderness in the right vault. No masses were felt.

A diagnosis of acute appendicitis was made, and an operation was performed the day of entry. Considerable dark blood was found in the pelvis and a ruptured hemorrhagic cyst the size of a small orange in the right ovary.

Comment This case is a good example of the symptomatology accompanying a ruptured cyst when the fulminating symptoms of acute hemorrhage are absent.

SUMMARY

Two hundred and fifty-seven cases of pain due to ovulation and its sequelae are analyzed.

Differentiation from appendiceal lesions is shown to be the most difficult step in diagnosis.

The closer the attacks approach to the onset of the next period, the more severe the symptoms usually are.

Appendicitis and pain consequent to ovulatory phenomena may exist simultaneously.

The large percentage of cases of ruptured corpus hemorrhagicum, if diagnosed definitely, may be treated without operation but the possibility of persistent bleeding necessitating surgical intervention must be kept in mind.

In women where a diagnosis of the milder forms of appendicitis is made and differentiation is not positive, a midline instead of a right-rectus or McBurney's incision should be made, in order to simplify exploration of the pelvis.

THE ESTIMATION OF THE NUTRITIONAL STATE IN CHILDREN*

MANUEL M. GLAZIER, M.D.†

BOSTON

THERE have been many attempts to secure a suitable formula for use in the rating of the nutritional state. Data for weight, height, sex and age,¹ for weight, body build, age and sex,² and for arm, chest and hip measurements³ have been suggested. Magee⁴ advocates the substitution of measurements of physical performance for those of physical development. Harris⁵ suggests that determination of specific deficiencies in the vitamins and in iron, by means of laboratory tests now available, could be used. These proposals have various degrees of value for studying the state of nutrition, but there is doubt of their being both adequate and practical.

Be this as it may, there is considerable confusion and difference of opinion regarding the estimation of the state of nutrition in children. This point was well illustrated by Dunstan,⁶ of England, in 1937, and by Derryberry⁷ in 1938. Both reported the results of surveys in which a specified number of experienced physicians or pediatricians independently examined the same group of children and determined their nutritional states. The results showed such wide individual variations that both authors perceived a pressing need for a more exact measure of the nutritional state. The purpose of this paper is to present such a standard of measurement, which has been developed as a result of observations in a large number of children over a five-year period.

MATERIAL AND PLAN OF INVESTIGATION

The subjects used in this investigation consisted of 556 children between the ages of two and twelve, who were followed from 1933 through 1937. One group was composed of 287 children who attended the first four grades of a primary school in Revere, and were for the most part from families whose yearly income was from \$1000 to \$2000. Another group included 269 consecutive cases from the Outpatient Department of the Boston Dispensary, which gives medical service to a comparatively low-income section of the population.

Information concerning the physiological symptoms in the school group was gathered by a group of students§ from the Tufts College Medical School who visited the children's homes. The rest of the study was done by me.

A suitable standard for the appraisalment of

the nutritional state in children should not only be based on accurate principles but should also be practical and applicable to and adequate for every child. Apparently these requisites are fulfilled in the co-ordination of the physical and physiological aspects of the nutritional state presented in the following scale, which was applied to all cases in this series.

- A Physiological aspect or functional symptoms
 - a. Appetite
 - b. Activity
 - c. Character of stools
 - d. Sleep
 - e. Frequency of infection
- B Physical aspect
 - a. Family tendency or inheritance
 - b. Physical development
 - 1. Interval gain in weight and height
 - 2. Physical examination

The combination of A and B determines the nutritional state.

The definition of nutrition as "a study of food-stuffs and the biochemical processes which utilize them"⁸ can be interpreted by saying that the state of nutrition of a child is equivalent to his growth and function. Since growth is analogous to physical aspect, and since function is closely related to physiological aspect, it was thought that a clinical measure of the nutritional state could be evolved by appraising separately and then co-ordinating both the physiological and the physical aspects of each subject.

The reflection of the physiologic processes was ascertained by taking a history of the appetite, activity, character of stools, sleep and frequency of infection. These symptoms were used as an index to body function and were called functional symptoms. Their proper interpretation required the analysis of each symptom as a complete unit, and as a link in the chain of the entire group.

The physical aspect of nutrition was evaluated from an estimate of the inherited trends and from the physical development of the child. The latter included the increment of growth (a history of the interval gain in weight and height) and the clinical evidence obtained from a physical examination. Special emphasis was placed on the state of the soft tissues and skeletal structure and the presence of foci of infection.

§Messrs. J. Guralnick, W. Lulow, G. Rothblatt and A. Wolbarsht.

CLASSIFICATION

As judged by the nutritional scale described above, the cases fell naturally into three groups those with good, fair and poor nutrition. The groups were compared with one another as regards appetite, sleep, familial tendency, foci of infection, dietary deficiency and age. There were 332 cases in Group 1, 151 in Group 2 and 73 in Group 3. Group 1 included the children with excellent physiological and physical aspects. This meant that the biochemical processes were proceeding correctly, or that a state of good health was present. Group 2 included the children with some impairment of either the physiological or the physical aspects. It represented a transitional or intermediate state, which might improve to one of good nutrition or regress to one of malnutrition. Group 3 included children with impairment of both the physical and the physiological aspects. Undoubtedly some abnormal circumstance had impaired the operation of the biochemical processes, and a state of poor nutrition was present.

PROGRESS OF CHILDREN WHOSE NUTRITIONAL STATE CHANGED

The study of 30 children whose state of nutrition changed during the years of this investigation showed that the first sign of improvement in children with malnutrition under treatment resulted in an improved physiological state. The appetite improved, sleep was more restful, the bowel

this change varied from several days to several weeks.

Fair nutrition became good nutrition when the child developed normal physical signs. This

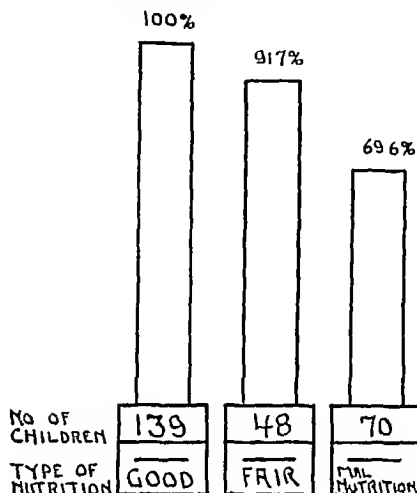

FIGURE 1 Percentage of Children with Adequate Appetites in Relation to the State of Nutrition

change usually required from four weeks to eight months.

Changing the child's nutritional state from good to fair required various periods of time, depend

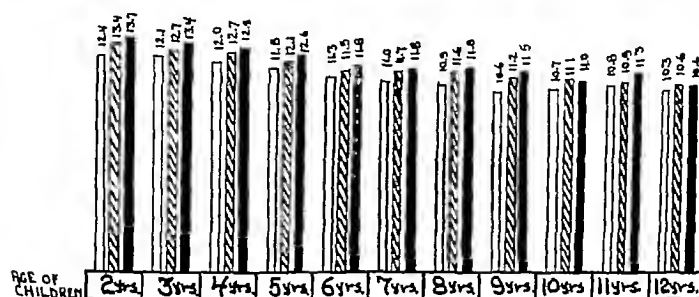

FIGURE 2 Required Daily Sleep in Relation to the State of Nutrition and to Age

movements became regular, and fatigue lessened or even disappeared. After the functional symptoms had become normal the malnutrition changed to fair nutrition. The period of time required for

ing on the degree of infection or the dietary deficiency. The first sign of regression was a change in the functional symptoms, with impairment of appetite, sleep, activity and the character of stools.

Continued regression resulted in poor posture, poor tissue turgor and other signs of malnutrition

ASPECTS OF NUTRITION

Physiological

There was a clear relation between a child's appetite and his nutritional state. All of 139 children with good nutrition had good appetites. Eight per cent of 48 children with fair nutrition had poor appetites, while 30 per cent of 70 children with poor nutrition had poor appetites (Fig 1)

Children with good nutrition in the same age group generally required less sleep than did those with malnutrition (Fig 2). From the age of two to nine years there was a difference of one hour. From ten to twelve years there was prac-

subject to familial tendency, age, time of year, sex and the presence of infection. The gain in weight varied from 3 to 16 pounds per year. Although not accurately determined, it appeared that the gain in children with good nutrition was greater than that in the others.

There appeared to be no special significance between height and the type of nutrition.

The distribution and amount of skin, fat and muscle frequently showed marked variations in each child. The kind of skin was not specifically related to the state of nutrition. The tone of both muscle and subcutaneous fat was excellent in children in good physical condition, while those in poor physical condition had soft or flabby tissue turgor. Children with fair nutrition had tissue turgor that ranged from soft and flabby up

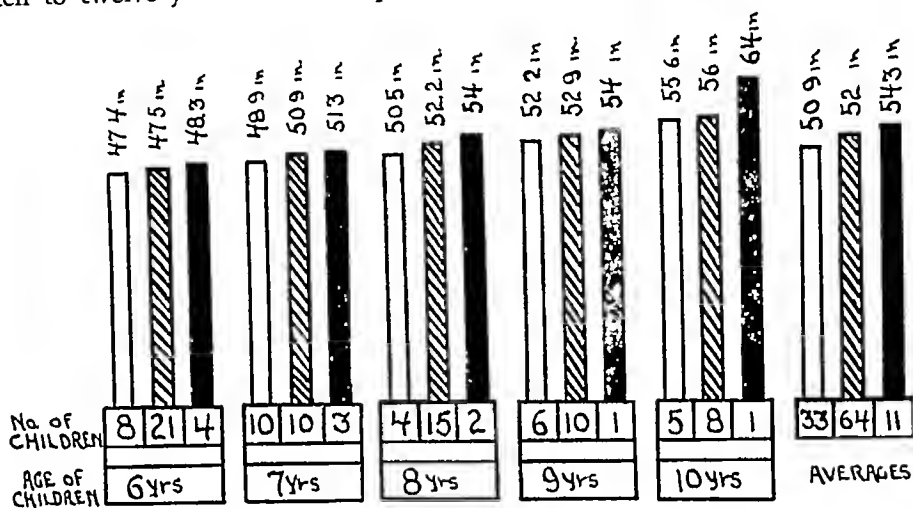

FIGURE 3 The Height of Children in Relation to That of Their Parents and to Age

The open blocks represent children with short parents, the cross-hatched ones those with parents of medium height, and the solid ones those with tall parents. The height of the blocks and the superimposed numbers represent the height of the children in inches.

ically no difference. In groups with similar nutrition there was only one hour's difference in the amount of sleep required daily between the ages of six and twelve.

Data concerning the frequency of infection and of fatigue in relation to the state of nutrition were not accurately recorded. However, it is our impression that infections and fatigue were distinctly more frequent in children with poor nutrition.

Physical

In the 108 children studied for the influence of heredity on height, the latter apparently followed the familial tendency in the majority of cases. However, 37 children were taller than the group average of children from parents in the next taller group (Fig 3).

The rate of growth was determined by observing height and weight changes over specific periods of time. These changes varied greatly and were

to the point when it became firm enough to be termed the equivalent of that in those with good physical condition.

The posture was usually dependent on the tissue turgor. In young children with poor tissue turgor resulting in the typical signs of poor posture, improvement in tissue turgor resulted in a gradual change to good posture. A distended abdomen was the last sign to disappear, and frequently years were required for this change to occur.

The relation between disease and the nutritional state was marked. Practically every child in the group with malnutrition had a focus of infection or a dietary deficiency (Fig 4). Thirty per cent of the outpatient children with fair nutrition had a focus of infection or a dietary deficiency. Forty per cent of the same group among the school children were similarly affected. Twenty-three per cent of the outpatient group with good

nutrition had a focus of infection or a dietary deficiency Seventeen per cent of the school chil-

ages the incidence of malnutrition gradually decreased, until it reached its minimum of 9 per cent at the age of eleven (Fig 5)

DISCUSSION

In determining the nutritional state each child was considered a clinical entity In attempting to interpret the physiological symptoms it was found that healthy children of the same group varied markedly in appetite, activity, sleep and gain in weight and height consequently they could not be judged by their group averages, which showed distinct variations This was illustrated by one six year-old boy with good nutrition, who required ten hours of sleep daily, while another boy of similar age and nutrition required thirteen

Intelligent interpretation of the physiological or functional symptoms requires their analysis both individually and as a group In this way proper emphasis can be placed on the exaggerated symptoms or those due to either an overestimation or an underestimation of a true functional state, both of which necessitate repeated visits in order to determine the true character of the symptoms

Heredity was found to influence definitely the type of skeletal structure in the child The familial tendency as regards the type of skeletal structure was determined by securing information about the skeletal structure of parents, grand parents, aunts, uncles, brothers and sisters The

age and the nutritional state, the incidence of malnutrition appeared to be greatest at the age of two, when it was 50 per cent. At succeeding

type of skeletal structure during childhood and early adulthood gives most accurate information, for the sedentary life of adulthood frequently re-

sults in the general deposit of a layer of subcutaneous fat that masks the true skeletal contour

SUMMARY AND CONCLUSIONS

In an attempt to develop a practical and accurate standard for the estimation of the nutritional state in children, 556 children between the ages of two and twelve were studied during a five-year period. The estimation of the nutritional states was accomplished by analyzing and coordinating the findings of the physical and the physiological aspects of each child.

Application of this procedure produced three nutritional classes, described as good, fair and poor. "Good nutrition" included children with good physical and physiologic states. "Fair nutrition" included children with either the physical or the physiologic state impaired. "Poor nutrition" included children with impairment of both the physical and the physiologic states. The nutritional state became better or worse as the physiological symptoms and the physical signs improved or regressed.

Although the majority of children followed a definite familial tendency so far as height was concerned, 34 per cent of them did not.

There were fewer complaints of poor appetite as the nutritional state improved. The required daily sleep in children with a better nutritional state averaged about one hour less than that in those with a poor nutritional state.

Foci of infection and dietary deficiency were present more frequently in those with poor nutritional states. However, 20 per cent of the children with good nutrition had an apparent focus of infection or a dietary deficiency.

Good nutrition, which was least common in early childhood, gradually increased with age and was commonest in later childhood. Malnutrition, which was commonest in early childhood, occurring in 50 per cent of cases at the age of two, gradually decreased with age until it reached 9 per cent at the age of twelve.

The results suggest that this standard is practical and applicable to and adequate for every child. Moreover, with definite guideposts to follow in the interpretation of the nutritional state, there should be less confusion and variation in results than are now present.

"COMMON COLDS"

NAOMI C TURNER, Ed 'M

ARLINGTON, MASSACHUSETTS

STUDIES among several groups of school children support the theory that a variety of microorganisms may act as the inciting agent in the production of upper-respiratory infections which are classed as "common colds." Groups of pronounced colds requiring numerous absences from school have been observed to appear consistently toward the end of the incubation period following the exposure of a class to a communicable disease spread through the secretions of the respiratory tract.

From October to June, I watched the interplay of colds and other communicable diseases in a nursery school of twelve pupils. Through the courtesy of the director, a daily notation was made for each child, throughout the school year, cover-

ing respiratory symptoms and the cause of any absence which occurred. The only series of colds for the entire year followed exposure of the children to chicken pox.

A three-year-old child attended school on November 5 and 6. The right nostril was red, and there was mucus in the left nostril. A diagnosis of chicken pox was made on November 7. On November 17, twelve days after the initial exposure, every other child in the class except two was kept at home for a cold. One of those remaining at school had mucus in the nostrils. The other had had chicken pox previously and went to bed with a cold one week later, the nineteenth day after exposure to chicken pox. We find, then, that within two or three weeks after exposure to

chicken pox every child in school had had a severe cold.

At no other time during the year did the group as a whole suffer from colds, nor were there any other cases of chicken pox, measles, scarlet fever, whooping cough, mumps or diphtheria. In several cases a child had sniffles or a cough which developed into a cold, but the infection did not affect the group as a whole.

This experience was sufficiently suggestive to make me think that observation of a larger group of children would be worth while. In a public elementary school, whose total enrollment was 598, I watched 160 children in the kindergartens and first grades from February 12 to May 28. In addition a second-grade class of 32 children was observed for a briefer period. The classes were followed during exposure to scarlet fever, measles and chicken pox. The same policy of notation for each child for each day was carried on.

In one kindergarten class of 33 children, which we shall call K_{Sa}, there were definite exposures to scarlet fever, measles and chicken pox. Here, too, the peak of respiratory symptoms seemed to come near the end of the incubation period of the disease to which there had been exposure. For example, seven days after the exposure of these children to scarlet fever by a child who vomited in the classroom and left school with a fever of 102°F, 12 children of this class exhibited symptoms of upper respiratory infection. Two other children developed scarlet fever within this week without further exposing the class.

The only other times when such a peak of upper respiratory symptoms was approached were fourteen days following a class exposure to measles, when 9 children had colds, nineteen days following an exposure to chicken pox, when 8 children showed respiratory symptoms, and twenty-one days following a second exposure to chicken pox, when the number again reached 8. These facts take on added significance when it is recalled that the incubation period for scarlet fever is from two to seven days, that for measles ten to fourteen days, and that for chicken pox two to three weeks.

It is interesting to note that on March 10, when among the 33 children in K_{Sa}, seven days after exposure to scarlet fever, there were 12 children exhibiting upper respiratory symptoms, the other four classes (124 children) which were being observed had a combined total of only 8 children either absent for a cold or showing upper respiratory symptoms.

The co-operation of the principal of this school, together with the help of the teachers and the school nurse, made it possible to continue observa-

tions during the next school year from September 8 to December 24 on a still larger group, made up of 318 children distributed among two kindergartens and three first grade, three second grade and three third grade classes. Causes of absences were noted, whether from communicable diseases, colds or otherwise, notations were also made of such upper respiratory symptoms as could be observed in the classroom during ten or fifteen minute daily visits.

During the period of observation, five classes participated in a definite measles epidemic. This fact makes the upper respiratory data difficult to follow. In general a peak of upper respiratory symptoms was found among the other children on the day that the new cases occurred. Five of six teachers in whose classrooms measles was prevalent were out with a cold from one day to a week during the period of the class exposure.

With the outbreak of measles in a classroom, it was noticed that upper respiratory symptoms were common among those who did not develop measles as well as among those who were coming down with the disease. Of 11 children known to be immune to measles in one second grade class, 6 had marked upper respiratory symptoms during the height of the epidemic. 3 had slight upper respiratory symptoms and 2 were well. In a first grade class which was subjected to two exposures to measles between March 21 and April 16, each of the 13 children immune to measles exhibited upper-respiratory symptoms.

During the fall of 1937 there was an incident in a fourth-grade class which is of interest. A boy was exposed to scarlet fever on September 9 by playing with a girl who on September 10 was diagnosed as having scarlet fever. He vomited on September 18, but was not otherwise known to be unwell except for having an earache. On October 14 he developed mastoiditis, for which he was taken to a hospital. There it was discovered that he was peeling, and a report was made to the principal that the boy had been attending school while having a mild case of scarlet fever. It is of interest to note what had occurred among his classmates. He was in school September 17 and also September 20 to 27, he was absent September 28 to have his ear treated. From September 20 to 29 11 children in this class of 37 pupils were absent with colds. At this time the other classes under observation in the school, from kindergarten through the third grade, were having excellent attendance, with very few absences on account of colds.

During the fall of 1937 a mild epidemic of chicken pox occurred in a first grade classroom of 29 children. On October 26, a boy was kept at

come with a diagnosis of chicken pox. Sixteen days from October 25, a second boy who sat diagonally in front of the first, began to show symptoms of chicken pox, and 8 other children either showed upper-respiratory symptoms in the classroom or were absent with colds. The third week after the first exposure to chicken pox, the class showed its maximum of absences for colds and upper-respiratory symptoms for any week from September 8 to December 24, 10 children had colds sufficiently severe to require home care. During this week among 289 children of the ten other classes being observed there were only 36 children who were absent for colds. Thus we see that with 10 absences from the first-grade classroom 34 per cent of the children were absent on account of colds, compared with 12 per cent in the ten other classes.

I recognize that no positive conclusions can be drawn from such data. But so frequently have the records shown an increase in the number of children having upper-respiratory symptoms toward the end of the incubation period following class exposure to certain communicable respiratory diseases that these organisms seemed to be indicated as the cause of such infections. This evidence suggests that the etiologic agents of various communicable diseases may manifest their presence, more frequently than is recognized, through symptoms usually thought of as those of the common cold.

Some of the recent public-health literature¹ suggests that the common cold is caused by a filterable virus, and that other organisms involved are always secondary invaders. In considering this filterable virus, it should be remembered that all that has been shown is that a single filterable virus can act as a causative agent in initiating cold-like symptoms. Common experience indicates that to accept the notion that a single virus is always the causative organism would lead to a false sense of security and many false expectations.

Certain well-recognized facts substantiate the belief that the causative organisms of upper-respiratory infections are various. In the first place, upper-respiratory symptoms may arise from several of the so-called "children's diseases." Measles is especially contagious when the catarrhal symptoms are manifest. Wagener² describes mild catarrhal attacks of measles during epidemics in adults who have had the disease. He believes these to be atypical cases. When measles appears first among aboriginal populations, it sweeps through them with a violence unknown among more civilized nations in which the disease has

been endemic for centuries. The symptoms of scarlet fever may be very mild; fever may be absent, the throat may be only slightly congested, and the eruption may be so slight as to be hardly recognizable. Yet mild as well as severe cases may be followed by serious sequelae. Scarlet fever is only one manifestation of streptococcal infection. It is well known that a typical case can infect a milk supply, with a resulting epidemic of septic sore throat. Adults and older children who have been exposed to scarlet fever sometimes develop only a simple tonsillitis.

In the second place, in all epidemics there are a large number of unrecognized cases. Such abortive and missed cases are commonly spoken of in epidemics of anterior poliomyelitis, scarlet fever, mumps, chicken pox, measles and whooping cough, and in the majority the presence of specific immunity can be demonstrated by proper laboratory procedures. In Palestine, colds are common but diphtheria and scarlet fever were once thought to be nonexistent. It has now been shown that both diphtheria and scarlet fever do occur, but in such a mild form that they were formerly unrecognized.³

Careful attention to the abortive forms of disease might help to interpret many so-called "colds." In pneumonia such unrelated bacteria as the pneumococcus and Friedlander's bacillus are able to cause very similar clinical and pathologic conditions. The possibility that various organisms are the etiologic agents for the common cold has important implications with respect to the care of colds. Perhaps physicians and parents who keep children at home and in bed for minor colds are in reality helping to abort other common communicable diseases which infect the upper-respiratory tract.

Special care of fatigue and attention to weather exposure near the end of the incubation period of a common communicable disease to which there has been exposure in the school, family or office may conceivably cut down the incidence of the common cold. If upper-respiratory infections called "colds" are due to various organisms, these infections will have different incubation periods rather than a constant one- to three-day period. The concept of the variable nature of upper-respiratory infections has far-reaching hygienic implications.

REPORT ON MEDICAL PROGRESS

GYNECOLOGY PELVIC PAIN AND ITS RELIEF

JOE V. MEIGS, M.D.*

BOSTON

BEFORE presenting descriptions of and techniques for the various methods described in the literature for relief of pelvic pain, it is necessary that an abbreviated review of the nerve supply of the pelvic organs be given, for it is only by cutting or chemically injuring such nerves that conduction in the sensory nerves can be checked. In the latter part of the paper the use of the roentgen ray and of cobra venom as means of alleviating pain will be briefly discussed. Ordinary lesions in the pelvis which cause pain that can be relieved medically or surgically, such as inflammatory processes, cysts (torsion), benign tumors and so forth, are not within the scope of this presentation. The pain to be considered cannot be corrected by the usual medical or surgical measures; it is caused by such conditions as primary dysmenorrhea, a tuberculous bladder or one involved in the so-called Hunner ulcer (interstitial cystitis) or is due to inoperable malignant disease or to the sequelae of such disease.

THE NERVES OF THE PELVIS

The nerves that supply the pelvic organs—the bladder, perineum, vulva, vagina and anal regions are included in the term—are of three types: somatic or cerebrospinal sympathetic and parasympathetic.^{1, 2}

The somatic nerves under consideration are the pudic nerve, which with its branch, the perineal nerve, supplies the perineal regions, and the lower thoracic and upper lumbar nerves, which transmit sensory stimulation from the peritoneum. The uterosacral ligaments, real sources of pelvic pain are supplied by the lower lumbar and sacral somatic nerves. Thus peritoneal and lower pelvic pains are somatic in origin, and operations on the sympathetic system will not give relief to this type of pain. An example of this is the attempt to relieve pain by superior hypogastric (presacral) neurectomy following conservative operations for endometriosis. Resection of the superior hypogastric plexus will take care of pain due to involvement of the uterine body but it will not relieve pain due to involvement of the posterior peritoneum or uterosacral ligament. Furthermore, as the sym-

pathetic nerve supply of the ovaries and tubes, which are often involved in the disease, arises from the inferior mesenteric and ovarian plexuses, excision of the superior hypogastric plexus should not and does not give relief. Thus the importance of accurate knowledge of the nerve supply is obvious.

The low thoracic and upper lumbar sympathetic ganglia receive sensory fibers from the uterus, tubes, ovaries, bladder, sigmoid and upper rectum. Interruption of these nerves should give relief from visceral pelvic pain. The upper vagina, cervix (probably), uterus and a part of the bladder give off sensory nerves which pass into the inferior hypogastric nerves, then to the superior hypogastric plexus (presacral nerves) and then to the cord in the lumbar and thoracic regions. The sigmoid, upper rectum, tubes and ovaries, on the other hand, send their sensory supply through the inferior mesenteric plexus. The ovaries and tubes are also involved in the ovarian plexus. Thus, section of the superior hypogastric plexus will not give relief from visceral pain in any of the above named organs.

The parasympathetic nerves (nervi erigentes) are sacral nerves and carry sensation from the bladder and possibly the lower segment of the uterus and the cervix. Thus, in severing the nerve supply of a painful bladder due to tuberculosis, cancer or a Hunner ulcer (interstitial cystitis), simple excision of the superior hypogastric plexus will not suffice. Section of the parasympathetic fibers as they make their exit from the sacral foramina would relieve this pain but would also cause bladder paralysis and therefore is out of the question.

Knowledge of the sensory fibers of these three different systems is necessary before one can intelligently predict what to expect from the various operations advocated for the relief of pelvic pain. Much has been done by many investigators toward an understanding of pelvic pain and its relief, and credit is due to Learmonth,³ Montgomery and Counsellor,² Leriche,⁴ Cotte,⁵ Davis,⁶ Wetherell,⁷ White,⁸ Smithwick,⁹ Greenhill and Schmitz,¹⁰ Beck,¹¹ Scott and Schroeder,¹² and many others. The various operations are discussed below, and in so far as is possible an attempt is made to evaluate their success and the reasons for it.

*Visiting surgeon, Massachusetts General Hospital; surgeon, Poodville Hospital, Massachusetts; Department of Public Health, instructor in surgery Harvard Medical School.

SECTION OF THE SOMATIC OR CEREBROSPINAL NERVES IN THE REGION OF THE PERINEUM

The painful itching of pruritus vulvae or kraurosis can be relieved by section of branches of the pudic nerve. This nerve divides into the perineal nerve and dorsal nerve of the clitoris. The perineal nerve divides into two branches, the first of which supplies the anal sphincter, and the other the perineum. This latter branch and its distal branches, important in perineal pain, are in contact with the posterior border of the transverse perineal muscle and run up over it to supply the perineum. Small branches proximal to the transverse perineal muscle also must be excised. These nerves may anastomose with others, such as the genitofemoral nerve, in supplying the perineum. Section of the nerves in this area, according to Learmonth, Montgomery and Counseller,³ will give relief to perineal pain, burning and itching.

SYMPATHECTOMY

Excision of the superior hypogastric ganglia (presacral nerves) is advocated for the relief of primary dysmenorrhea. This operation, first suggested and reported by Cotte,⁶ consists of resection of the superior hypogastric plexus in the retroperitoneal area from the bifurcation of the aorta to that of the iliac arteries. The operation interrupts sensory fibers coming from the uterus. It does two other things: it allows a marked vasodilatation of the vessels of the uterus, since the sympathetic fibers are inhibitors and cause vasoconstriction, and it improves the tone of the uterine musculature, for with sympathetic inhibition removed the power of the parasympathetic system to increase tone is given full freedom. Pain sensation from the uterus itself may be considered as due to contractions in an attempt to pass menstruum through a tight cervix or to the contraction of an ischemic or an underdeveloped uterus. In some cases this operation relieves pain in the bladder, especially if the pain is due to a lesion in the central part of the bladder floor or in the region of the trigone. It does not relieve the backache which accompanies dysmenorrhea, for on dilating the cervix after successful sympathectomy backache can still be produced.¹³ Thus the nerve supply of at least part of the cervix is not sympathetic in origin. In cancer, if the pain is due to uterine distention or stretching, this operation will give relief, but if the pain is due to involvement of the uterosacral ligaments or cervix, or to infiltration of the pelvic lymph nodes and the retroperitoneal regions, it is of no avail.

When resection of the superior hypogastric plexus is combined with removal of the lumbar

ganglia, a greater relief can be expected, for this operation interrupts a part of the inferior mesenteric plexus and, therefore, sensation of the sigmoid and upper rectum, a part of the tubes, and the ovaries. Only visceral pain can be relieved by excision of these nerves.

EXCISION OF THE SACRAL PARASYMPATHETIC NERVES

The neurones of the parasympathetic nerves run in the anterior divisions of the second, third and fourth sacral anterior nerves and enter the pelvis through the sacral foramina. The rami of these nerves, the nervi erigentes, pass through the inferior hypogastric ganglia. The nervi erigentes cause vasodilatation and increase bladder tone and open the internal sphincter. They also contain sensory neurones. Removal of the inferior hypogastric ganglia will relieve obstinate pelvic pain, but will paralyze the detrusor muscle and thereby prevent voluntary emptying of the bladder. The exclusion of parasympathetic action through resection of the inferior hypogastric ganglia should be used only in extreme cases or in those where a fistula is present. Combined with superior hypogastric neurectomy it will stop nearly all painful impressions coming from a tuberculous or cancerous bladder, but bladder paralysis must be expected.

ALCOHOL INJECTION

Two methods of injecting alcohol into the subarachnoid space have been suggested. In the first, the injection is done one side at a time, with the patient lying on one side or the other,¹⁰ and in the second (White⁸), the injection of the alcohol is made with the patient in the prone position with the hips elevated. The alcohol injures the sensory fibers of the dorsal roots. This eliminates pain from the region supplied by those roots. It is usually stated that alcohol injection rarely causes injury to motor fibers, since they are more resistant to alcohol than are the sensory fibers. In the first method the patient is placed on her side on the operating table, with the hips elevated by means of a pillow or sandbag. She faces slightly ventrally, thus elevating the region of the dorsal or sensory roots. A lumbar puncture is done in any interspace from the first to the fourth or fifth lumbar, and 0.5 to 0.7 cc of 95 per cent ethyl alcohol is injected. The patient is kept in this position for one or two hours. If the injection is satisfactory it will relieve pain in the pelvis on the side injected. Injection of one side is occasionally sufficient, but it is usually necessary to inject the other side at another time in the same way, thus blocking the dorsal roots on both

sides. Sometimes the function of the bladder is interfered with so that incontinence occurs, and injury to motor roots may result, with subsequent leg weakness. White advocates placing the patient in the prone position with the hips elevated—the old Kraske position. The injection of 10 to 12 cc. of sterile absolute alcohol is made between the fourth and fifth lumbar vertebrae or between the fifth lumbar and first sacral vertebrae. The alcohol, being lighter than the spinal fluid rises to the uppermost level of the spinal cord and injures the dorsal roots of the third, fourth and fifth sacral nerves. This gives an anesthesia of the vulva, perineum and bladder (parasympathetic supply), as well as the region of the anus and any other structures supplied by these nerves.

The type of pain for which such treatment is used occurs in women with vulval, vaginal or cervical cancer. No damage is done to the motor fibers running to the legs, but the anal sphincter is often damaged. Inability to urinate may be expected from the injection, because of the injury done to the parasympathetic nerves (nervi erigentes). Thus it is well to reserve low sacral cord injection for those patients who have bladder fistulas or incontinence.

These methods for relief of pelvic pain are successful in so far as they go, and all regions supplied by the lower lumbar and sacral nerves can be relieved by one or the other. It must be remembered, however, that pelvic regions supplied by uninjured lower thoracic or higher lumbar nerves and all regions supplied by sympathetic fibers are not relieved by this method. Sympathetic fibers which supply the viscera with sensation are not injured because of the fact that they enter the cord in the lumbar or thoracic areas. Thus, for pain due to carcinoma in the vulva or perineum and for that due to involvement of the lumbar and sacral nerves and the regions they supply, including the uterosacral regions, the cervix, the lower peritoneum, the vagina and so forth these methods of treatment are available, but for pain due to a lesion of the upper pelvic peritoneum, anterior or posterior, and for visceral pain alcohol injection is of no use. Schroeder⁴⁴ suggests combining the removal of the sacral sympathetic ganglia and of the superior hypogastric plexus and intrathecal injection of alcohol in order to obtain relief from bladder pain. Section of the sacral sympathetic nerves is not considered of much value in relief of pelvic pain. Incidentally in the Pondville Hospital, relief of pain due to cancerous extensions by this type of treatment has not been so satisfactory as that claimed by the various authors on the subject. The lumbar pain secondary to involvement of the ureter, with

consequent hydronephrosis, hydronephrosis and pyonephrosis, is not relieved by alcohol injection. Such pain is often low down in the flank and even in the suprapubic region. By study of the genitourinary tract this pain must be differentiated from that due to kidney lesions. Alcohol injection has its place in the treatment of pain due to malignant disease, but for benign lesions other methods of attack should be used.

CORDOTOMY

By cordotomy is meant the section of the anterolateral or spinothalamic tract in the cord. This is done after first exposing the cord by means of a laminectomy. The rationale of the operation is the interruption of those fibers in the cord that carry the sensations of pain and temperature. No motor fibers should be injured in this operation, though at times, owing to too radical an incision in the cord, section of some is inadvertently done. All visceral pain is not always relieved by this operation, because some of the visceral sympathetic fibers are deep in the cord and others ascend in different tracts. However, the persistence of pain is not a common occurrence, and if the operation has been done on both sides and the incision is carried deep enough, complete relief is usually obtained.

Cordotomy is often considered too formidable except for the unrelievable pain of cancer, but in some cases with intractable pain in the pelvis due to other lesions that cannot be approached surgically it is of great value. The relief of the excruciating pain of bladder cancer or that caused by involvement of the perineural lymphatics in the pelvis is possible by this means. This operation done on one side affects the contralateral side and, if the fibers are cut deep enough, gives anesthesia almost up to the level of the incision. To obtain a proper result the operation is usually done in the upper thoracic cord. There is seldom any permanent urinary difficulty resulting from the operation, as the somatic and the sympathetic motor fibers are not injured. Cordotomy is usually successful, and it is not done frequently enough or early enough in those patients that have incurable cancerous lesions. The operation is usually put off until the patient can no longer bear her pain, even with morphine, and is in poor condition. Then the operation is of very major consequence. Earlier and more frequent cordotomies should be used in those patients who are obviously going to die of their disease.

ROENTGEN RAY TREATMENT

It has long been known that roentgen ray treatment of metastatic cancer may be of value in elim-

inating pain for varying periods of time. It is probably not possible to cure cancer in the pelvis by means of such treatment, but reduction in the size of the metastatic lesions that have involved the pelvic nerves or are blocking the proper drainage of the pelvic viscera, thus causing visceral distention, is often possible. The latter is a frequent cause of pelvic pain. It is also true that involvement of bone with cancerous extensions is amenable to roentgen-ray treatment. When patients with cancer have masses that can be felt in the pelvic or broad ligaments, or when bone metastases are located by roentgenograms, the effect of roentgen-ray treatment should be tried. Often the relief from pain is great and tumor masses regress, but just as often no relief is obtained and the tumors grow in spite of all attempts to check them. It is then necessary to look to other methods of relief, such as alcohol injection or cordotomy.

COBRA VENOM

Recently, owing to the work of Macht¹⁵ and others, cobra venom has been used to check pelvic pain caused by cancer and its extensions. In adequate dosage there is no doubt that mild pain may be relieved and that patients thus avoid the possibility of becoming drug addicts. Its success in patients with pain due to invasion of retroperitoneal spaces, perineural lymphatics and bone is not so great, and failure in a large percentage is certain. However, there is no doubt that the use of large doses, as advocated by Rutherford,¹⁶ — the saturation of the patient with two to three ampules per day for seven to ten days, — will give an indication of whether its further employment is justifiable. If cobra venom can be used to replace or to supplement morphine it will be recognized as a very valuable method for combating pelvic pain.

DISCUSSION

All three nerve supplies to the pelvis — somatic, sympathetic and parasympathetic — are involved in pelvic pain. It is necessary to understand these nerve supplies in order to evaluate the various procedures outlined to check pain. In general, the removal of the visceral rami will relieve visceral pain, and alcohol injection will alleviate somatic pain, but each method may be entirely useless for the other type of pain. Cordotomy, which should relieve all pelvic pain, can miss visceral or sympathetic pain. Alcohol injection will relieve somatic or parasympathetic pain but not sympathetic. Local sections of cutaneous nerves are of value in the treatment of certain lesions, but

the exact nerve supply of each painful area must be fully understood before such sections are undertaken. Pelvic pain may be due to distention of a viscus or to a pull on it, while invasion may cause no pain at all. Inflammation of the pelvic peritoneum may cause backache (involvement of the lumbar or sacral nerves) or abdominal pain (involvement of the thoracic or intercostal nerves), depending on whether the posterior or anterior peritoneum is involved. Flank pain may be due to dilatation of the kidney pelvis because of ureteral obstruction secondary to cancer or fibrosis. The pain due to retroperitoneal connective tissue or peritoneal involvement can be relieved by alcohol injection, but flank pain due to renal involvement cannot.

CONCLUSIONS

An understanding of the nerve supply to the pelvis and its viscera is essential in the treatment of pelvic pain. Sympathectomy, alcohol injection and cordotomy are each successful and have reasons therefor.

The use of roentgen rays is helpful in pelvic pain but rarely of enduring value.

Cobra venom will surely take its place in the attack on pain, because it is analgesic without being habit-forming.

Earlier and more frequent use of cordotomy is advocated for patients whose malignant lesions cannot be cured.

CASE RECORDS OF THE MASSACHUSETTS GENERAL HOSPITAL

ANTHEMORTAL AND POSTMORTAL RECORDS AS USED
IN WEEKLY CLINICOPATHOLOGICAL EXERCISES

FOUNDED BY RICHARD C. CABOT

TRACY B. MALLORY, M.D., *Editor*

CASE 26051

PRESENTATION OF CASE

A sixteen year-old girl was admitted to the hospital complaining of headache.

About three weeks before admission the patient began having moderately severe, gradually increasing left frontal headaches, occurring usually in the afternoon and associated with occasional spells of dizziness. She had no other complaints and continued to attend school regularly until five days before entry when she fell while in the bathroom and struck the back of her head. When found by her mother a few moments later she was lying on the floor unconscious. She became conscious about ten minutes later, complaining of severe headache, neck pain and malaise. There was no scalp wound. A few hours later double vision, nausea, persistent vomiting and a stiff neck appeared. Three days before admission the patient was admitted to an outside hospital where examination revealed bilateral papilledema and a xanthochromic spinal fluid under 500 mm of water pressure, roentgenograms of the skull were reported as negative. She was transferred to this hospital for further studies.

Physical examination revealed a well-developed and nourished girl who was acutely ill. The skin was hot and dry. She complained of severe headache and pain in the back of her neck. The neck was hyperextended and stiff, with a positive Kernig. There was no localized skull tenderness or scalp wound. Examination of the heart, lungs and abdomen was negative. The pulse was irregular with numerous extrasystoles. The sensorium was clear. The blood pressure was 104 systolic, 66 diastolic. The eyes were tender, and there was increased ocular tension. There was moderate choking of both optic disks, more marked on the left, though the disk outlines could be made out, the veins were engorged, but no hemorrhages were noted. The visual fields were normal. The pupils were dilated and slightly unequal and reacted sluggishly to light and accommodation. There was weakness of horizontal outward motion of each eye, but no nystagmus. On opening the mouth the jaw deviated toward the left. The remaining cranial-nerve functions were normal. The reflexes were depressed but equal, an equivocal Babinski sign was found on the right.

The temperature was 102°F., the pulse 80, and the respirations 24.

Examination of the blood showed a red-cell count of 4,200,000 with 70 per cent hemoglobin (Tallqvist) and a white cell count of 13,500 with 85 per cent polymorphonuclears. The urine examination was negative. Blood Hinton and spinal fluid Wassermann tests were negative. Numerous spinal-fluid studies showed the following: there was xanthochromia, and the initial pressures ranged from 350 to 500 mm of water, the total protein readings were 50, 58, 103, 24, 29 and 21 mg per 100 cc., and the number of red blood cells 446, 495, 70, 4 and 4 per cubic millimeter, respectively, the white blood cells ranged from 94 to 0 per cubic millimeter. The sugars, chlorides and gold-sol determinations were essentially normal. A tuberculin (dilution 1:10,000) skin test was positive.

An electroencephalogram monopolar recording showed slow waves (3 and 4 per second) in the right frontal region and to a certain extent in the left frontal region. There was also some slow wave activity in the left occipital region. There was marked difference between the two sides, the left showing considerably more abnormal activity than did the right. Attempts to locate the source of this abnormal rhythm were not very successful, as it seemed to shift from the left occipital to the left frontal region. The report stated that the dominant rhythm was mixed with slow waves and that the voltage was slightly increased, localization of the lesion was questionable. Roentgenograms of the skull showed that the convolutional markings were not increased, the pineal gland was not visible. There were no unusual areas of calcification. The sella turcica appeared slightly deeper than usual. There was, however, no erosion of the clinoid processes, and it was thought possible that the appearance of sella was due to a congenital abnormality. Eleven weeks later repeat skull plates showed an increased irregularity of the sella, the posterior clinoid processes were tilted upward and appeared sharp. The coronal suture was relatively wide. There was no convolutional atrophy, and no areas of calcification. Ventriculograms taken thirteen weeks after entry showed dilatation of both lateral ventricles, as well as of the third ventricle. There was an unusually long pineal recess. Neither the aqueduct nor the fourth ventricle filled with air. The third ventricle showed slight displacement to the right. A 3.0 by 4.5 cm. mass was seen to protrude into the left ventricle and appeared to arise from the general position of the choroid plexus.

The patient ran a temperature of 101°F. for the first week of her illness, thereafter it was normal.

During this time sixteen lumbar punctures were performed for the relief of intracranial pressure. The left supraorbital nerve was novocainized for the relief of pain in the left forehead and nose. The neurological findings remained essentially the same, except that transient diplopia and slight lateral nystagmus with occasional right facial weakness appeared. Following ventriculostomy, the patient developed a severe frontal headache, with pain, numbness and weakness of the left hand and arm. The latter findings disappeared two hours after their onset, but the headache persisted. She was given x-ray therapy, 200 r daily for a total of 1200 r, to the lesion in the lateral ventricle. On the one hundred and twenty-fourth hospital day an operation was performed.

DIFFERENTIAL DIAGNOSIS

DR H HOUSTON MERRITT * This is a very unusual case and there is little in the history or examination to localize this lesion or to help us in determining its nature. Since study of the record indicates that the lesion was localized by encephalogram I should like to see the films before discussing the case further.

DR JAMES R LINGLEY The films were essentially negative, as the record states, except for some deepening of the sella turcica. The floor is pushed down slightly, and there is some questionable thinning of the dorsum and posterior clinoid processes. On the other hand, there is no increase in the convolutional markings, and no appreciable separation of the sutures. On the ventriculogram, however, the tumor was very well outlined. Here we have a moderately dilated left lateral ventricle. Projecting into the body of the ventricle you can see a sharply defined, smooth, rounded tumor defect. It is exactly in the region of the genu of the choroid plexus. Here you see the dilated third ventricle and the enlarged suprapineal recess, there is no filling of the aqueduct. There is definite evidence of a tumor projecting into the left lateral ventricle, and in view of the hydrocephalus and the failure of filling of the aqueduct, I should suspect there is an extension downward, which obstructs the aqueduct.

DR MERRITT Do you believe that this was a tumor and not a hematoma into the choroid plexus?

DR LINGLEY That was the differential we considered at the time. We have seen a number of hematomas of the choroid, as described by Dyke,¹ but we have never seen any so large as this one.

DR MERRITT That is the location where hematomas occur, is it not?

DR LINGLEY Yes, exactly.

DR MERRITT There is no doubt from the history that this patient was suffering from intracranial disease, but there is very little in the clinical history to help us localize the lesion. Significant factors on the examination that might help are also strikingly absent. Most of the signs given here are those one sees with increased intracranial pressure—dilated pupils that sluggishly react to light, and weakness of the outward motion of each eye, which is due to weakness of the sixth nerves.

What is the site and nature of this patient's lesion, and is the abnormality seen in the x-ray the actual lesion? In the first place it is obvious that associated with whatever abnormality existed there was also hemorrhage. The patient was relatively well until just a few weeks before the onset of the disease, and even then she was evidently not sick enough to be kept at home and attended school. The onset, with coma, was very dramatic, and when the patient became conscious there were signs of meningeal irritation—stiffness of the neck and hyperextension—and lumbar puncture performed at another hospital showed a xanthochromic fluid. It does not state whether it was a slight or marked degree of xanthochromia or how many, if any, red blood cells were present in the fluid. When examined here a few days later, the signs of meningeal irritation were still present and the spinal fluid was still xanthochromic and contained a small number of red blood cells, with some white cells, which were probably the result of irritation of the blood or possibly secondary to the presence of a tumor. It is noted that the tuberculin skin test was positive. That may have some significance. The electroencephalogram did not seem to help in localizing the lesion, it was believed that there was probably more abnormality on the left, but also some on the right. The ventriculogram showed, in addition to the mass, a shift in the position of the third ventricle. I should like to ask Dr Lingley if he considers this to be of a significant degree?

DR LINGLEY Yes, there is also a definite elevation in the floor of the lateral ventricle on this side in the posterior portion of the third ventricle.

DR MERRITT We have to consider then what lesions in this location could give such a symptomatology. The ventriculogram did not show the aqueduct or the fourth ventricle. This may have been due to one of two factors: first, these structures sometimes are visualized very poorly in a ventriculogram, second, it may be, as Dr Lingley has pointed out, that a tumor is extending downward and shutting off the aqueduct, thus prevent-

*Assistant professor of neurology, Harvard Medical School, acting head of the Department of Neurology, Boston City Hospital.

ing the filling of the fourth ventricle and producing a hydrocephalus

What kind of tumors occur in the lateral ventricle? The commonest ventricular tumors are colloid cysts, but they occur only in the third ventricle, since they probably represent rests of the paraphysis. The tumors that do occur in the lateral ventricle are various. They may be hemangiomas or meningiomas of the choroid plexus, and sometimes there are carcinomatous metastases to the choroid plexus. However, this may not be a primary tumor of the choroid plexus, but primary in the brain and extending out into the ventricle. The brain tumors that extend out into the ventricle are chiefly the ependymomas, which arise from the ventricular lining and may also extend into the brain. It is conceivable that a polar spongioblastoma or astrocytoma might also do the same.

I should be happy about the diagnosis of tumor if there had not been such a dramatic onset to the symptoms. With the exception of slight disability three weeks before the patient was well. The sudden onset suggests intracerebral hemorrhage, however, it hardly seems possible for an intracerebral hemorrhage to produce this type of ventricular disturbance. If we could be sure the lesion shown in the ventriculogram is not a hemorrhage into the glomus caused by the trauma of ventricular puncture then we could exclude cerebral hemorrhage. But if it is a hemorrhage into the glomus secondary to ventriculography cerebral hemorrhage must be considered. Where could a hemorrhage originate in order to give these symptoms? In the first place, hemorrhage in a sixteen-year-old girl is rare, but not unknown. Parenthetically, tumors in the hemisphere of a girl of this age are also rare. There is nothing to indicate that this patient could have had hemorrhage into the hemisphere of the brain. There was no paralysis, no aphasia and no disturbance of the visual fields. Could she possibly have had hemorrhage into the cerebellum? That could cause a dilatation of the ventricular system and the symptoms that she had. It is extremely unusual for a person with a hemorrhage in the hemisphere or into the cerebellum to live as long as this patient did—one hundred and twenty-four days. Hemorrhage of any size usually kills before that time. It is possible that the lumbar punctures prevented such an occurrence. I believe that the two most likely diagnostic possibilities are primary tumor of the nervous system, extending into the ventricular system, and intracranial hemorrhage, probably in the cerebellum. The latter diagnosis does not explain the pushing up of the left lateral ventricle and the shadow

in the ventricle, unless we say it is not a tumor but hemorrhage due to puncture. I think, however, that we have to take the x-ray evidence first and say that the shadow is a tumor and that this patient had a neoplasm of the brain which extended into the ventricular system and was probably a primary tumor of the choroid plexus with some hemorrhage from the tumor.

DR. JAMES B. AYER. I am a little surprised that Dr. Merritt did not include in his differential diagnosis the commonest cause of hemorrhage, namely spontaneous meningitic hemorrhage from an aneurysm. It was this diagnosis which was entertained for many weeks, for although there was intermittent hemorrhage the choked disks receded. It was only after a long period that we were convinced that this diagnosis could not be further entertained and we were willing to accept the hazards of a pneumoencephalogram to demonstrate a possible tumor.

Personally I was surprised when the evidence for tumor was substantiated.

DR. W. JASON MIXTER. I think what Dr. Ayer says is perfectly true so far as it concerns the patient when she entered the hospital. At the same time I believe that after knowing the entire story particularly the x-ray findings Dr. Merritt's contention that one need not take into consideration subarachnoid hemorrhage is correct. Probably we ought to have considered neoplasm earlier than we did on account of the fact that the tumors of the lateral ventricle are prone to show very little in the way of symptomatology. We have been fooled on several of them. I do not know what the pathologic process was, and I shall be interested to hear. In one of the other cases in which I have been particularly interested the diagnosis is still in doubt and lies between intrinsic tumor of the brain itself and endothelial sarcoma.

DR. TRACY B. MALLORY. Will you tell us about the operation, Dr. White?

DR. JAMES C. WHITE. There were two operations. When this patient came in here, the spinal fluid pressure was nearly 500 mm. She was losing vision very rapidly, and we did a ventriculogram, as there were no satisfactory localizing signs. This disclosed a round tumor in the posterior portion of the left lateral ventricle. Dr. Kubik then showed us a specimen in the museum with a history that was almost identical with this—intermittent bleeding and a tumor in the same region which was so vascular that any attempt to operate would have caused death on the operating table. That was a hemangioma of the choroid plexus, with great vessels, some nearly 0.5

cm in diameter, and it was attached to the brain over a wide area, especially over the thalamus. We therefore gave this girl x-ray treatment in the hope that it might decrease the vascularity, but the pressure became so high we thought we would have to do a palliative operation to drain the obstructing hydrocephalus if we were going to keep on with radiation. Dr Jost Michelsen performed a ventriculostomy, as described by Stookey and Scarff.² That was successful inasmuch as it reduced the pressure from 600 to 300 mm., and she made a smooth recovery. But it became apparent on account of the size of the tumor that x-ray treatment was going to lower the pressure no further and that she would get gradual loss of vision and blindness. We therefore decided to tackle the main growth no matter how risky it might be. It was discussed with the family. One difficulty was that the tumor was in the dominant left hemisphere, and it was obvious that you could not avoid going through the back of the temporal lobe around the region of the supramarginal gyrus, which would produce a type of aphasia with difficulty in reading and forming ideas.

A bone flap was turned out over that area and the cortical vessels looked unusually large, so a biopsy was taken. The area selected to go through was about a centimeter below the Sylvian fissure. We had to make an opening 3 or 4 cm. long to expose the tumor, which lay about 1 cm. below the surface. There were no vessels going into it, and we had to go in to a depth of 7 cm. before we got to the central end of the tumor. We worked our way in carefully, wiping the brain away, and could identify normal veins on the medial side of the posterior portion of the ventricle. There were also large communications to the choroid plexus, which had to be clipped. Following the removal of the mass there were some interesting disturbances in the blood pressure. At first the systolic pressure fluctuated from 60 to 80, and then during the closure, for no reason fell so low that it could not be obtained. A transfusion was given. During the next two days there were periods of tachycardia, fluctuation of blood pressure and a temperature of 105°F., without any evidence of infection and no polymorphonuclears in the spinal fluid. The patient was in deep coma. All these signs are attributable to injury of the hypothalamus. There was also a right hemiparesis, which we thought was due to postoperative edema of the internal capsule. If you should superimpose the tumor on a normal brain you would see that it must have run far forward as well as medially. These changes are straightening out now, and the patient has

her eyes open and follows you around with them, but is not yet speaking.

It is now ten days since operation, and it is time for the edema to begin disappearing. We hoped that she would be in better condition and more mentally awake than she is. She is rallying from the operation well, and we hope with time that the aphasia will not be too severe.

CLINICAL DIAGNOSIS

Hemangioma of the left choroid plexus

DR MERRITT'S DIAGNOSIS

Hemangioma of the choroid plexus of the left lateral ventricle

ANATOMICAL DIAGNOSIS

Hemangioma of the left choroid plexus

PATHOLOGICAL DISCUSSION

DR CHARLES S KUBIK The specimen from another case led to the diagnosis of hemangioma of the choroid plexus here. The former patient was a girl of fifteen. At autopsy there was a large intraventricular mass, most of this was old blood clot, but a small portion showed a cavernous hemangioma. There was a small hemangioma of the choroid plexus in the other lateral ventricle. The tumor that Dr White removed was an encapsulated semifluctuant tumor, weighing 46 gm. The capsule was very thick and firm. The inside of the mass was filled with blood clot, in which there was organization in the outer part, although the mass has been cut up in rather small pieces we have been unable to find any hemangioma inside of the capsule. There was some other tissue removed, however, in which there are numerous thin-walled blood vessels—unquestionably hemangioma of the cavernous type.

We have had one or two cases of hemangioma of the choroid plexus in infants. It is one of the less common causes of spontaneous subarachnoid hemorrhage, and in our autopsied cases we have had 3 or 4 with hemangioma of the choroid plexus as against about 25 with intracranial aneurysm. Looking back over the case now there was a clue, I suppose, in the fact that this patient already had papilledema when admitted, only a few days after the episode in which she lost consciousness. It is true, to be sure, that she had had headaches for about three weeks before that.

DR MERRITT I should like to add that the reason I did not suggest spontaneous hemorrhage was that there was not enough blood in the spinal fluid to consider primary subarachnoid hemorrhage.

DR KUBIK Yes, that is another feature which was different from the picture usually seen in cases with subarachnoid hemorrhage.

CASE 26052

PRESENTATION OF CASE

First Admission A thirty-one year-old man was admitted to the emergency ward complaining of epigastric pain.

About three or four days before admission the patient suddenly had an attack of left upper quadrant and epigastric abdominal pain. The attack followed a heavy meal, and was associated with much belching and nausea, but with no vomiting or marked anorexia. He stated that a similar episode occurred four years before entry. He was then seen in an outside hospital where a diagnosis of ulcer was made, but without x-ray studies. He allegedly passed one tarry stool two years before admission, but none since. A blood Hinton test done seven years before entry was negative.

The patient had been a chronic arthritic for some twenty five years, and for twelve years had led a bed-and-chair existence. There were no other illnesses, past or present.

Physical examination revealed a thin, poorly developed and nourished, bedridden man whose spine was rigid, with a slight upper dorsal kyphosis. There were moderate flexion deformities of the elbows, hips and knees, with accompanying muscle group atrophy. Examination of the heart and lungs was negative. The epigastrium was slightly tender, but without spasm. The remainder of the physical examination was normal, as were the blood and urine. The blood pressure was normal.

The temperature, pulse and respirations were normal.

A gastrointestinal x-ray series showed no evidence of disease in the esophagus. The stomach had prominent mucosal markings and quite active peristalsis. In the lower part of the antrum on the side of the greater curvature there was a round, rather lobulated, small hemispherical, intramural, extramucosal tumor which measured 2.5 cm. in length and 1.5 cm. in height. The pylorus opened readily, filling a normal duodenal cap. He was discharged from the emergency ward on the second hospital day.

Second Admission (six months later) Four days before entry the patient was suddenly seized with an attack of nausea, followed shortly by the vomiting of recently ingested food. Since that time he had continued to vomit 'everything' he ate, the vomiting usually occurring about one or two hours after the ingestion of food. His upper abdomen became tender and distended. He was able to pass gas by rectum, but no bowel movements had occurred since his first attack of nausea. The physical examination was unchanged from that above, except that his abdomen was distended and tympanitic, with diffuse tenderness, most marked in the epigastrium. Peristalsis gave a high-pitched note and was not heard except at infrequent intervals.

The blood showed a white-cell count of 8500. The serum chlorides were equivalent to 95 cc of N/10 sodium chloride per 100 cc, and the serum protein was 6.6 gm per 100 cc. A flat x-ray film of the abdomen showed several air filled dilated loops of small intestine, visible particularly in the right lower abdomen. The colon was air filled but not distended. With Wangenstein drainage, enemas, parenteral fluids and a blood transfusion the patient improved. About twelve days after admission an exploratory laparotomy was performed.

DIFFERENTIAL DIAGNOSIS

DR CLAUDE E. WELCH May I see the x-ray films?

DR. AUBREY O. HALSTON The filling defect described in the lower third of the stomach on the greater curvature is quite obvious in these films. It does appear to be extraluminal, but you can rarely be quite sure that a tumor is submucosal because the mucosa is stretched over the lesion so tight that one cannot always recognize it. So far as I can say, this one is very likely to be submucosal. It does not look like a polyp. It is a sessile appearing intramural defect. The mucosa around it is absolutely normal. The film taken on the second admission does show signs of small-bowel ileus or obstruction. The colon contains gas, and so does the stomach. The small bowel is enormously dilated. There is also some dense substance that looks like bismuth in the colon. I do not believe there is evidence of obstruction in the colon.

DR. WELCH So the initial diagnosis is easy. It is quite obvious that we are dealing with a tumor of the stomach plus superimposed intestinal obstruction. From this point on we progress on rather thin ice because quite a number of probabilities and possibilities have to be discussed.

Is there anything in the past history that would be of any advantage in this discussion? I expect

that his two previous attacks of pain were due to a lesion that will be discovered in the bowel rather than to the one in the stomach. We can obviously rule out the diagnosis of ulcer, and I think we had better regard the tarry stool with a good deal of suspicion because it is not confirmed by any other test. At the time of admission, in the emergency ward, we have no data of interest except for the x-ray examination. The commonest lesion in the stomach in that location is a leiomyoma or possibly a leiomyosarcoma. Two other things to be considered are neurofibroma, which occasionally occurs within the wall, and pancreatic rest, although the mass is large for the latter. We should also consider polyp, which I think we can rule out by the x-ray picture. Carcinoma, if we can trust the x-ray report, which is usually the most accurate part of the record, we can rule out. The possibility of lymphoma remains and must be seriously considered. The picture, of course, is unusual for that of lymphoma in that the tumor is well localized without induration of the wall surrounding it, on the other hand, a submucosal lymphoma must be kept in mind.

Apparently this disease had been progressive or he had developed some other disease when he came in with intestinal obstruction. The stomach tumor may have been an entirely different lesion from the one that was producing intestinal obstruction, on the other hand, the two may be related.

Let us proceed then with a diagnosis of intestinal obstruction and see if we can rule in a diagnosis that might coincide. In the first place, the obstruction of the small bowel, judging from the amount of gas-filled intestines we see, was probably low in the ileum, furthermore it was not a complete obstruction, for there is gas in the colon and gas was passed quite freely by rectum. I do not believe we have any evidence to indicate that this was a paralytic ileus, because peristalsis persisted and he had a white-cell count of 8500 and, I assume, a normal temperature. In other words there was a mechanical obstruction of some type.

If we consider the causes of mechanical intestinal obstruction we can rule out several of them immediately. The commonest, of course, is hernia. There was no evidence externally, and internal hernias are so rare we can drop them from our discussion. Could it have been a foreign body of some type, a food bolus or a gallstone? The previous attacks of abdominal pain would make one consider gallstone. On the other hand, about half the gallstones that obstruct the small bowel are visible on flat plates of the abdomen. We see no area of density here. Furthermore, the patient lived for twelve days and apparently improved.

That would be highly improbable with gallstone obstruction, which usually progresses rapidly to lethal exitus unless the stone is removed. Could it have been volvulus? The patient was alive twelve days afterward, volvulus would undoubtedly by that time have led to infarction and peritonitis. The attack was not typical of intussusception in any respect. A mesenteric thrombosis seems to be ruled out by the normal white count, by the blood pressure and by other features that are not typical.

So we are left with two types of obstruction that we need to consider seriously. One is that due to bands or adhesions of some type and the other is that due to tumor. Obstructions due to adhesions usually follow abdominal operations. This man had not had a previous operation. He conceivably could have had congenital adhesions or some band arising around the base of a Meckel's diverticulum. But we have no positive evidence to lead to that diagnosis. What kind of tumors would produce such an obstruction? If this was in the lower ileum, the commonest tumors we have to deal with are lymphoma, leiomyoma, fibroma, carcinoma and carcinoids. Of that entire group lymphoma is the commonest. The fact that lymphoma is frequently a multiple tumor and the fact that there was also a tumor in the stomach incline us somewhat toward that diagnosis. Leiomyomas frequently produce gross intestinal bleeding, a symptom for which we have no evidence. Again, if I am going to make one diagnosis cover both lesions, it is unusual to have two leiomyomas in the same patient. Fibroma of the lower bowel rarely attains sufficient size to produce intestinal obstruction. Primary carcinoma of the lower ileum is possible but is not so common as it is in the jejunum or duodenum. A carcinoid is a rare tumor which is frequently multiple, but it is extremely rare in the stomach. So it is with a great deal of trepidation that I come down to a final diagnosis that will cover all the difficulties in this patient. I have ruled out all the common things such as carcinoma of the stomach, with metastases, bands and adhesions, and I should say that we are dealing with multiple tumors, which, on the law of chance, will prove to be lymphomatous.

DR. RICHARD H. WALLACE. This man had two extremely unusual and entirely unrelated findings. The first operation was done for small-bowel obstruction, the nature of which we did not know. The point of obstruction was in the pelvis. The whole abdomen was filled with not only greatly dilated but greatly thickened loops of small bowel, such as are found in cases with chronic obstruc-

tion The terminal ileum was entirely collapsed The obstruction was produced by a large Meckel's diverticulum which contained about 300 cc. of liquid fecal material and was distended to the thinness of a rubber balloon There was no evidence of inflammation, and no adhesions The diverticulum was entirely free, with no twist or impairment of blood supply, and in lifting the tip all the fluid very readily ran back into the bowel

This is especially interesting to me because in 1933 Dr Richard H Miller and I* looked up all the cases of Meckel's diverticulum in this hospital, and of the cases that had symptoms over 85 per cent had obstruction and of all the latter there was not a single case with a non-inflammatory or non-adherent diverticulum

We removed the diverticulum, then felt the pyloric end of the stomach which seemed very much as described by x ray, there being a 2.5-cm rubbery smooth mass, which seemed to be in the wall of the stomach We thought it was probably a leiomyoma and felt that it ought to be removed Approximately three weeks later we re-explored the patient and did a subtotal resection

CLINICAL DIAGNOSES (PREOPERATIVE)

Small-bowel obstruction
Leiomyoma of stomach

DR. WELCH'S DIAGNOSIS

Malignant lymphoma of stomach and ileum

*Miller R. H., and Wallace R. H.: Meckel's diverticulum I. acute abdominal emergencies. *A. S. S. S.* 96:713-721 1933

ANATOMICAL DIAGNOSES

Meckel's diverticulum, with intestinal obstruction.

Ectopic pancreas (adenomyoma) of stomach

PATHOLOGICAL DISCUSSION

DR. TRACY B. MALLORY When the resected portion of the stomach was examined it was apparent that the mucosa had been elevated over a considerable area by an underlying intramural tumor The mucosa itself was normal except for a small but clearly visible dimple overlying the central part of the tumor On section it was evident that the tumor was circumscribed but not encapsulated and involved submucosa, muscularis and even serosa On microscopical examination it was found to consist of irregularly intertwining bundles of muscle fibers surrounding small groups of epithelial cells Most of these consisted of ducts or glands lined with high columnar, mucous-secreting epithelium similar to that seen in the ducts of the pancreas One area contained recognizable gastric epithelium with clearly apparent chief cells No pancreatic acinar cells were found, but in the depths of the tumor were several characteristic islands of Langerhans, so the pancreatic nature of the rest appears established beyond doubt.

These are the tumors which have often, in the past, been described as adenomyomas Occasionally only the rather non-specific ducts are present, but usually some other pancreatic elements can be identified if enough sections are cut. The inclusion of functioning gastric epithelium is, in my experience, quite unusual

PROBLEMS BEFORE THE MEDICAL PROFESSION

THE development of medical knowledge, technology and material appurtenances during relatively recent years could hardly have been expected to occur without resulting in many changes in the practice of medicine. A similar development has occurred in other fields of human endeavor where advances in science have resulted in increased effectiveness. These developments not only have provided new implements, new methods and new products but also have effectively changed industrial and commercial organization and social and political economy.

One sees in retrospect the growth of scientific knowledge as the progress of man's control over natural forces, the development of his environment, and the acquisition of an independence from supernatural and traditional authority. In the Renaissance

there were the voyages of the great explorers, the flowering of art and commerce, the Protestant Reformation. Vast countries were opened up, industrial revolution occurred, national dependency declined. In this environment the seeds of democracy germinated, and democracy flowered best in America where the opportunity for expansion provided the ideal conditions for the social expression of individual equality and independence. Later when the frontier had gone and America came of age, followed a period of consolidation and organization, a supplementation by mechanization, instrumentation of the no longer expansive graphic environment. New advances in technology still contributed to man's control over natural forces, to bigger and better tools and products but they entailed a dependence of man on himself on the ever-increasing instruments of production. The economic independence of the individual declined. And in so far as has occurred, the democracy of individuality which developed as the social expression of individual equality and opportunity, no longer reflects the social demands. Trusts and corporations grow to provide the machinery of production. Unions and co-operatives develop to protect the interests of the individuals. Society takes a form and government a function that limit the rights of individuals.

Medicine has not and probably cannot escape this general trend. It is faced with problems of consolidation and organization. As medicine and practice have developed, the equality and independence of physicians have been lost as witnessed, for example, by the prevalence of so-called "closed staffs." And just as individuals in other walks of life have created organizations to cope with the increasing intricacies of their occupations, so physicians have developed medical societies, clinics, group practices and specialties. And, paradoxically enough, these attempts to solve the problems which have threatened the independence and individuality of physicians have in many ways infringed upon them. But the clock cannot be turned

Neither will it avail to stand aside pointing to the record of the past, while society, intent on its struggle with the present, moves on

If the medical profession is to direct its future course, it must face reality. And in so doing, it is well to remember that the present problems concerning the distribution of costs and organization of medical service arise from the very developments that have contributed to the advance of medicine in the past. Unless these problems are considered with a tolerance and judgment which are consistent with constructive action toward their solution, further advances may be impeded. For, if the consideration becomes a contention of prejudice and emotion, little progress will be made, much harm may be done, and the problems will remain

COMMUNITY FUND CAMPAIGN

As this issue of the *Journal* goes to press, the success of the 1940 Community Fund Campaign is being shaped by Greater Boston's people. A minimum of \$4,625,000 must be reached by February 6

At the end of the first day, the Physicians Group showed a 17 per cent increase over its contribution of last year, thus doing a fine job toward making this year's campaign the biggest ever. Each physician should have a genuine sense of personal responsibility for the success of the Fund. Only in this way can the goal be attained, and the Community Fund must succeed, since it is vital to the well-being of the people of Greater Boston

MEDICAL EPONYM

BABINSKI'S PHENOMENON

Joseph Babinski (1857-1932) described this sign in the *Comptes rendus hebdomadaires des séances et mémoires de la Société de biologie* (48 207, 1896). The title of the article is *Sur le réflexe cutané plantaire dans certaines affections organiques du système nerveux central* [Plantar cutaneous reflex in certain organic affections of the central nervous system]. The translation of a portion of the article is as follows

I have observed in a certain number of cases of hemiplegia or monoplegia involving the leg which were associated with an organic affection of the central

nervous system, a disturbance in the plantar reflex of which I here present a short description. On the healthy side, pricking of the sole of the foot causes a flexion of the thigh on the pelvis, the leg on the thigh, the foot on the leg, and the great toe on the metatarsus. This also occurs in normal persons. On the paralyzed side, a similar stimulus also gives rise to a flexion of the thigh on the pelvis, the leg on the thigh, the foot on the leg, but the great toe instead of being flexed is extended on the metatarsus

PUERPERAL INFECTION FOLLOWING NORMAL DELIVERY

Mrs. F. H., a twenty-eight year-old woman, on the morning of August 12, 1936, five days after a normal delivery of her second baby had had a chill, followed by a temperature of 103°F and a pulse of 120

The family history was irrelevant. The patient's past history was negative except for a tonsillectomy. Catamenia began at twelve and had ever been regular until her marriage. Her last period had begun on November 2, 1935, making her expected date of confinement August 9. The previous pregnancy had ended in a normal delivery on July 1, 1935 but the baby lived only six weeks.

The recent pregnancy had been normal throughout. She was delivered normally of an 8 pound, 12 ounce, female child after median episiotomy. The placenta and membranes were delivered intact and there was no bleeding after delivery.

Convalescence was normal until the fifth post partum day, as stated above. Examination at that time showed the uterus not enlarged. There was an indefinite deep mass in the left breast. The lochia was sticky and dark, and a stained smear showed gram positive cocci in chains and gram negative bacilli; a culture yielded hemolytic streptococci and colon bacilli. That afternoon the temperature came down to 100.4°F and then went up to 104. On August 13 the morning temperature was 102.8°F, in the afternoon it rose to 102 with a pulse of 120. The next day the temperature was normal and remained so throughout the rest of the hospital stay. Because of the short duration of the temperature, conservative treatment was instituted. The baby did not nurse.

A series of selected case histories by members of the section will be published weekly. Comments and questions by subscribers are solicited and will be discussed by members of the section.

Comment The sudden rise in temperature five days post partum, while unusual in puerperal infection, is not uncommon. The source of the infection was discovered by bacteriological examination. At the onset of the fever there was an indefinite lump in one breast which might have led one to think that the breast was responsible. However, for a temperature of 104°F on the fifth day following delivery to be caused by a breast infection is most unusual. The uterus was normal in size, it was not tender. There was no tenderness in the abdomen. The lochia was not normal, it was sticky and dark-colored, and the smear and culture showed the infective agents. The treatment was entirely conservative so far as the uterus itself was concerned. Ice was applied to the fundus, and Ergotrate was given by mouth. Consultation with a bacteriologist was held, the question of administering sulfanilamide was gone into, but the short duration of the clinical symptoms seemed to make this unnecessary. The patient has since had another baby, with a perfectly normal convalescence.

DEATHS

BRIGHAM—FRED C. BRIGHAM, M.D., of Springfield, died January 22. He was in his seventieth year.

Born at Fayston, Vermont, he attended Green Mountain Seminary at Waterbury, Vermont, and the State Normal School at Randolph. He received his degree from Baltimore Medical College in 1898, and started practice in Salisbury and Jamaica, Vermont. Before going to Springfield he practiced in Westfield.

He was a member of the Massachusetts Medical Society, the American Medical Association, the Springfield Academy of Medicine, the Hampden County Medical Association, the Eastern Hampden Medical Society and the New England Society of Physical Medicine. Dr. Brigham retired from active practice in 1934.

His widow, two daughters and a sister survive him.

BURNHAM—J. FORREST BURNHAM, M.D., of Lawrence, died January 26. He was in his seventy-second year.

Dr. Burnham attended Harvard University and received his degree from the Harvard Medical School in 1901. He was a fellow of the Massachusetts Medical Society and the American Medical Association. From 1914 to 1920 he was an alternate delegate and from 1920 to 1936 a delegate to the House of Delegates of the American Medical Association, and he had served as secretary of the Essex North District Medical Society. Dr. Burnham was secretary of the staff of the Lawrence General Hospital for many years and was a member of the Lawrence Medical Club.

His widow survives him.

PREBLE—WILLIAM E. PREBLE, M.D., of Boston, died January 22. He was in his sixty-fifth year.

Born in Litchfield, Maine, he attended Bowdoin College and received his degree, cum laude, from Harvard Medical School in 1909. In 1925 he received an honorary degree from Bowdoin College.

Dr. Preble was a former instructor at Tufts College Medical School and had served as head of the medical department at the Boston Dispensary. He was a fellow of the Massachusetts Medical Society and the American Medical Association.

His widow and a daughter survive him.

STIVERS—GEORGE L. STIVERS, M.D., of Tucson, Arizona, died November 26, 1939. He was in his sixty-third year.

Dr. Stivers received his degree from the Long Island College of Medicine in 1899. He was a fellow of the Massachusetts Medical Society and the American Medical Association.

His widow survives him.

MISCELLANY

MOTOR-VEHICLE DEATHS FOR 1939

Motor vehicle deaths in one hundred and fifty-one major cities decreased 4 per cent in 1939 from the previous year, however a decrease of 10 per cent was reported for the first six months, according to reports made public recently by Director William L. Austin, Bureau of the Census, Department of Commerce. Deaths for 1939 totaled 8009, compared with 8376 for 1938, a decrease of 367. These percentage decreases are based on provisional figures for 1939 and 1938.

Considering only those deaths in each city due to motor vehicle accidents occurring within the city limits, the 1939 reports showed a total of 5641 deaths. This figure is a decrease of 222 deaths, or 3.8 per cent, from the 5863 deaths reported for the same cities in 1938. The decrease in the total is reflected in the individual cities, eighty-one of which showed a decrease in the number of deaths from 1938, sixty-two showed increases, and eight cities had the same number.

Six of the cities having populations of 500,000 or more and showing decreases in the number of deaths occurring within the city are New York City (2.8 per cent), Los Angeles (7.6 per cent), Cleveland (16.6 per cent), St. Louis (26.6 per cent), Boston (5.6 per cent), and Pittsburgh (8.5 per cent). Seven cities having similar populations and showing increases over the 1938 figures are Chicago (0.5 per cent), Detroit (5.5 per cent), Baltimore (8.8 per cent), San Francisco (14.0 per cent), Milwaukee (26.8 per cent), Buffalo (1.2 per cent), and Washington (7.5 per cent).

CORRESPONDENCE

LICENSE REVOKED

To the Editor The license of Dr. Simeon Weiner, 167 Pleasant Street, Worcester, was revoked by the Board of Registration in Medicine on January 18, because of participation in the production of premature termination of pregnancy.

STEPHEN RUSHMORE, M.D., *Secretary*.

State House,
Boston

FEDERAL INSURANCE BENEFITS FOR SURVIVORS

To the Editor No one is more familiar with the family problems caused by death than the doctor in whose care the family has entrusted its well-being. Beyond the sorrow and personal bereavement, the doctor is only too

painfully aware of the economic problems which the death of a breadwinner may bring to a family. Yet, in many cases, he is powerless to assist when more than his own medical services are needed.

The new provisions of Federal Old Age and Survivors Insurance, effective January 1, 1940 may have an abiding interest for doctors as a means of eliminating, or at least reducing substantially, the economic misfortunes occasioned, in many cases, by death. A brief summary of those provisions which might be of special interest to the general family practitioner follows.

New survivors benefits are payable on the death of an insured wage earner after December 31 1939. In contrast with the old-age payments after the age of sixty five, survivors benefits are payable without regard to the age of the deceased. In all cases, the person on whose wages the benefits are based must have been a wage earner in business or industry after 1936 and must meet the eligibility requirements. Detailed information of these requirements may be obtained from any of the forty-four field offices of the Social Security Board located in the principal cities of New England.

The kinds of survivors benefits are as follows:

- (1) Monthly cash benefits for insured wage earner's widow after the age of sixty-five, until she remarries or dies.
- (2) Monthly cash benefits for insured wage earner's widow regardless of age, while she has in her care the deceased's unmarried dependent children under the age of sixteen or under the age of eighteen if still attending school.
- (3) Monthly cash benefits for insured wage earner's unmarried dependent child or children under the age of sixteen, or under the age of eighteen if still attending school.
- (4) Monthly cash benefits for insured wage earner's dependent parents, after the age of sixty-five if no widow or child under the age of eighteen, survivors.
- (5) Lump sum if insured wage earner leaves no survivors immediately entitled to monthly benefits.

The following table gives examples of survivors' monthly benefits according to wage, years of coverage and number of dependents.

| AVERAGE MONTHLY WAGE OF DECLASSED WORKER | ONE CHILD, OR PARENT 65 OR OVER | WIDOW 65 OR OVER | WIDOW AND ONE CHILD |
|--|---------------------------------|------------------|---------------------|
| WITH 3 YEARS OF COVERAGE | | | |
| \$50 | \$10.30 | \$15.45 | \$25.75 |
| 100 | 12.87 | 19.31 | 32.18 |
| 150 | 15.45 | 23.17 | 38.62 |
| 250 | 20.60 | 30.90 | 51.50 |
| WITH 5 YEARS OF COVERAGE | | | |
| \$50 | \$10.50 | \$15.75 | \$26.25 |
| 100 | 13.12 | 19.69 | 32.81 |
| 150 | 15.75 | 23.62 | 39.37 |
| 250 | 21.00 | 31.50 | 52.50 |
| WITH 10 YEARS OF COVERAGE | | | |
| \$50 | \$11.00 | \$16.50 | \$27.50 |
| 100 | 13.75 | 20.60 | 34.37 |
| 150 | 16.50 | 24.75 | 41.25 |
| 250 | 22.00 | 33.00 | 55.00 |

Complete information on this subject may be obtained by directing the inquiry to the Social Security Board Field Office at the nearest of the following locations:

Connecticut—Bridgeport, Hartford, Meriden, New Britain, New Haven, New London, Stamford, Torrington, Waterbury and Willimantic.

Maine—Augusta, Bangor, Lewiston and Portland.

Massachusetts—Attleboro, Boston (120 Boylston Street or 40 Central Street), Brockton, Cambridge,

Chelsea, Dorchester, Fall River, Fitchburg, Haverhill, Holyoke, Lawrence, Lowell, Lynn, Malden, New Bedford, Pittsfield, Quincy, Salem, Springfield, Waltham and Worcester.

New Hampshire—Concord, Littleton, Manchester, Nashua and Portsmouth.

Rhode Island—Newport, Pawtucket, Providence and Woonsocket.

Vermont—Burlington, Montpelier and Rutland.

JOHN PEARSON, *New England Regional Director*
Social Security Board.

TESTS FOR SYPHILIS DURING PREGNANCY

To the Editor: A considerable number of physicians have inquired of this department as to how they should proceed under the law requiring serological tests for syphilis in pregnancy when the patient refuses to permit a specimen of blood to be taken.

Obviously no physician can compel a patient to permit the specimen to be taken or take it forcibly without being liable to suit for assault. On the other hand, the law directs the physician to take the specimen but does not compel the patient to permit it to be taken. We have advised those physicians who have inquired as follows:

(1) If the physician desires to continue to care for the patient, he may request that she give him a statement in writing to the effect that she refuses to have the specimen taken and accepts personal responsibility for any accident to her pregnancy or the infection of her infant with syphilis which may result from failure to have the blood test done.

(2) If the physician would rather not assume any responsibility in the matter, he may inform the patient that she had better seek medical care elsewhere. It might be well to confirm that advice to the patient in writing.

Unless the physician protects himself through some such means as this, it is conceivable that he might be sued for failure to take the test if the patient produces a syphilitic child or has an accident to her pregnancy on the basis of her infection with syphilis.

N. A. NELSON, M.D., *Director*
Division of Genitoinfectious Diseases,
Massachusetts Department of Public Health.

State House,
Boston.

TYPHOID VACCINE

To the Editor: Typhoid vaccine (monovalent) instead of typhoid-paratyphoid B vaccine, will be distributed routinely by the Department of Public Health after March 1 1940. This is in accordance with the action of the Public Health Council, which action was prompted by the low incidence of paratyphoid B fever. The monovalent typhoid vaccine should cause fewer reactions than the bivalent and should fulfill the chief purpose of immunization against enteric fever.

For a time at least, the typhoid-paratyphoid B vaccine will be available on special request, but will not be sent otherwise.

PAUL J. JAKMAUTH, M.D.
Commissioner of Public Health

State House,
Boston.

UNITED STATES PHARMACOPOEIAL CONVENTION

To the Editor The public scientific conferences will be held simultaneously at the Willard Hotel, Washington, District of Columbia, during the afternoon and evening of Monday, May 13, the day preceding the opening of the 1940 Pharmacopoeial Convention. The programs are being developed under the direction of the General Chairman of the Committee of Revision aided by the chairmen of subcommittees and advisory boards and will be presided over by the subcommittee and advisory board chairmen.

All who are interested in perfecting the pharmacopoeial monographs are invited to take part in these advance conferences. The greatly increased importance of the scope and the standards of the *Pharmacopoeia* to medicine and surgery, to pharmacy in all its divisions, and to the enforcement officials of the federal and state governments calls for the widest collaboration from those who are interested in pharmacopoeial standards.

Those who can participate in this program should write to the specific subcommittee or board chairman responsible for the subjects in which they are interested. The chairmen are listed in the *Pharmacopoeia*. If preferred, the subject to be presented may be sent directly to the General Chairman of the Committee of Revision, and the chairman of the particular conference covering the subject will be immediately notified.

E FULLERTON COOK, *General Chairman*,
U S P XI, Committee of Revision

43rd Street and Woodland Avenue,
Philadelphia

NOTICES

BOSTON DOCTORS SYMPHONY ORCHESTRA

The Boston Doctors' Symphony Orchestra will rehearse under Alexander Theide, former concertmaster with the Cleveland Symphony Orchestra and the Philadelphia Symphony Orchestra, every

Thursday at 8 30 p.m., in Studio A, Station WMEX, 70 Brookline Avenue, Boston. Those interested in becoming members should communicate with Dr Julius Loman, Pelham Hall Hotel, Brookline (BEA 2430).

SOUTH END MEDICAL CLUB

The next meeting of the South End Medical Club will be held at the headquarters of the Boston Tuberculosis Association, 554 Columbus Avenue, Boston, on Tuesday, February 20, at 12 o'clock noon. Dr Edward A Edwards will speak on "The Common Diseases of the Veins".

Physicians are cordially invited to attend.

TUMOR CLINIC, BOSTON DISPENSARY

Each Tuesday and Friday morning, 10 00 to 12 30, there is a meeting of the Tumor Clinic of the Boston Dispensary, a unit of the New England Medical Center. Neoplasms of various sorts are seen and discussed, and when there is an indication, are treated with radium of high voltage x-ray. Physicians are invited to visit this clinic. They may bring patients for aid in diagnosis or may refer patients to the clinic following which a report

will be returned to the referring physician. A limited number of beds are available for diagnostic study and for treatment.

BOSTON LYING IN HOSPITAL

The Journal Club will hold a meeting at the Boston Lying in Hospital on Tuesday evening, February 13, at 8 15. Dr W E Caldwell will speak, his subject being "The Obstetric Pelvis".

JOSEPH H PRATT DIAGNOSTIC HOSPITAL

The following talks will be given in the auditorium of the Joseph H. Pratt Diagnostic Hospital during the week of February 4.

Monday, February 5, at 4 30 p.m. Cancer of the Stomach. Dr George Pack, of the Memorial Hospital, New York City.
Discussion by Dr Howard M Clute.

Thursday, February 8, at 4 30 p.m. Tumors of the Bone. Dr Bradley Coley, of the Memorial Hospital, New York City.
Discussion by Dr Channing C Simmons.

Reticulum-cell Sarcoma of Bone. Dr Channing C. Simmons.

Physicians are cordially invited to attend these lectures.

JOSEPH H PRATT DIAGNOSTIC HOSPITAL

Bennet Street, Boston
Lecture Hall, 9-10 a.m.

MEDICAL CONFERENCES

Friday, February 2—The Diagnosis of Multiple Myeloma. Dr B M Jacobson.

Saturday, February 3—Hospital case presentation. Dr Thannhauser.

Tuesday, February 6—Skin Cancer. Dr F M Thurmon.

Wednesday, February 7—Hospital case presentation. Dr Thannhauser.

Thursday, February 8—Gynecological Cancer. Dr L. E. Phaneuf.

Friday, February 9—Hodgkin's Disease. Drs. William Dameshek and Isadore Olef.

Saturday, February 10—Intrathoracic Cancer. Drs R. H. Overholt and R H Betts.

Tuesday, February 13—Hospital case presentation. Dr Thannhauser.

Wednesday, February 14—Clinicopathological conference. Dr C S Keefer.

Thursday, February 15—Title to be announced. Dr A A Thibodeau.

Friday, February 16—Some Observations on Pituitary Adenomas. Dr M C Sosman.

Saturday, February 17—Hospital case presentation. Dr Thannhauser.

Tuesday, February 20—Paralysis Agitans. Dr H. I Harris.

Wednesday, February 21—Hospital case presentation. Dr Thannhauser.

Friday, February 23—Epidemiology of Respiratory Infections. Dr Dwight O'Hara.

Saturday, February 24—Hospital case presentation. Dr Thannhauser.

Tuesday, February 27—Suppurative Disease of the Lungs. Dr L. F Davenport.

Wednesday, February 28—Hospital case presentation. Dr Thannhauser.

Thursday February 29—The Medical Social and Preventive Aspects of a Selected Case. Preceptors and medical students.

PETER BENT BRIGHAM HOSPITAL

A joint medical and surgical clinic at the Peter Bent Brigham Hospital will be held on Wednesday February 7 from 2 to 4 p.m. Drs. Robert Zollinger and William P. Murphy will speak on "Menorrhagia." A clinicopathological conference conducted by Dr. Elliott C. Cutler will take place from 4 to 5 p.m.

On Thursday February 8, from 8.30 to 9.30 a.m. there will be at the Peter Bent Brigham Hospital, a combined clinic, conducted by Dr. Charles A. Janeway of the medical, surgical, orthopedic, and pediatric services of the Children's Hospital and the Peter Bent Brigham Hospital. Physicians and students are cordially invited to attend.

WILLIAM HARVEY SOCIETY

A meeting of the William Harvey Society of Tufts College Medical School will be held in the auditorium of the Beth Israel Hospital Boston on Friday evening February 9 at 8.00. Dr. Albert N. Richards will speak on "Kidney Function." The meeting will be conducted by Dr. David Rapport.

Interested members of the medical profession and their friends are invited to attend.

GREATER BOSTON MEDICAL SOCIETY

A meeting of the Greater Boston Medical Society will be held in the auditorium of the Beth Israel Hospital on Tuesday evening February 6, at 8.15. Clinical papers will be presented by members of the staff of the New England Medical Center.

PROGRAM

- Group Psychotherapy Dr. Herbert I. Hartis.
 Carcinoma of the Rectum. Dr. William M. Shedden.
 Hyperlipemia. Dr. S. J. Thanhauser.
 Anorexia Nervosa or Hypopituitarism? Dr. Samuel Proger.
 "What We Can and Cannot Do in Allergy" Dr. Ethan A. Brown.

NEW ENGLAND DERMATOLOGICAL SOCIETY

The next meeting of the New England Dermatological Society will be held on Wednesday February 14 at 2.00 p.m. at the Massachusetts General Hospital. There will be a dinner following the meeting.

UNITED STATES MARINE HOSPITAL

The staff meeting of the United States Marine Hospital, Chelsea will be held at "The Hut," on Wednesday afternoon, February 7, at 4.00 p.m. Dr. Henry D. Chadwick will talk, his subject being "Epidemiology of Tuberculosis."

UNIVERSITY EXTENSION COURSES

To help prepare young people for work as medical secretaries and to assist dental hygienists in learning up-to-the-minute information on health education, the Massachusetts Department of Education has scheduled two university-extension courses, namely "Training for Doc-

tors Secretaries" and Public Health Education for Dental Hygienists."

The secretarial course consisting of eight lectures, will be given by Dr. Robert M. Green, associate professor of applied anatomy at Harvard Medical School. In these lectures Dr. Green will consider the following basic medical sciences: anatomy, hygiene, physiology, pathology, pharmacology, dietetics and nutrition. The class will meet on Tuesdays, at 7.30 p.m. starting February 6 in Sever Hall Harvard University Cambridge.

The course on health education will consist of fifteen lectures and will be given by Miss Jean V. Latimer, coordinator of health education, Division of Child Hygiene, Massachusetts Department of Public Health and instructor in health education, Hyannis State Teachers College (summer session) and by Dr. Florence B. Hopkins, dental pediatrician, Massachusetts Department of Public Health. The course will be held at the Forsyth Dental Infirmary for Children, 140 Fenway Boston, beginning Friday February 9 at 7.15 p.m.

Registration may be made at the first meeting of each class or to insure enrollment, at the office of the Division of University Extension, State Education Building, 200 Newbury Street, Boston.

AMERICAN ASSOCIATION FOR THE STUDY OF GOITER

The next annual meeting of the American Association for the Study of Goiter will be held at Rochester, Minnesota April 15, 16 and 17. The program for the three-day meeting will consist of papers dealing with goiter and other diseases of the thyroid gland, dry clinics conducted by guests of the association, and operative clinics conducted by the staff of the Mayo Clinic.

SOCIETY MEETINGS AND CONFERENCES

CALENDAR OF BOSTON DISTRICT FOR THE WEEK BEGINNING SUNDAY FEBRUARY 4

- SA. Y. FEBRUARY 4
 4 p.m. Facts and Fancies About Heart Disease. Dr. Paul D. White. Free public lecture. Harvard Medical School, amphitheater of Building D.
 4 p.m. Heart Disease. Dr. Barton E. Hamilton. Illustrated, public, health lecture. Fulkner Hospital auditorium.

- MONDAY FEBRUARY 5
 12.15-1.15 p.m. Clinicopathological conference. Dr. S. Burt Wolbach, Peter Bent Brigham Hospital amphitheater.
 4 p.m. Physics and medical students are cordially invited to attend a clinic presented by the medical, surgical and orthopedic services of the Infants and Children's Hospitals in the amphitheater of the Children's Hospital.
 4.30 p.m. Cancer of the Stomach. Dr. George Pack. Joseph H. Pratt Diagnostic Hospital.

- TUESDAY FEBRUARY 6
 9-10 a.m. Skin Cancer. Dr. Francis M. Thurman. Joseph H. Pratt Diagnostic Hospital.
 10 a.m.-12.30 p.m. Boston Dispensary tumor clinic.
 12.15-1.15 p.m. X-ray conference. Dr. Merrill C. Souman. Peter Bent Brigham Hospital amphitheater.
 8.15 p.m. Greater Boston Medical Society. Beth Israel Hospital auditorium.

- WEDNESDAY FEBRUARY 7
 New England Pediatric Society. Children's Hospital amphitheater and Longwood Towers.
 9-10 a.m. Hospital case presentation. Dr. S. J. Thanhauser. Joseph H. Pratt Diagnostic Hospital.
 12 m. Clinicopathological conference. Children's Hospital amphitheater.
 4 p.m. Joint medical and surgical clinic. Peter Bent Brigham Hospital.

- THURSDAY FEBRUARY 8
 8.30-9.30 a.m. Combined clinic of the medical, surgical, orthopedic and pediatric services of the Children's Hospital and the Peter Bent Brigham Hospital and the Peter Bent Brigham Hospital.

- *9-10 a.m. Gynecological Cancer Dr Louis E. Phaneuf Joseph H Pratt Diagnostic Hospital
 *4 30 p.m. Tumors of the Bone Dr Bradley Coley Joseph H Pratt Diagnostic Hospital

FRIDAY FEBRUARY 9

- *9-10 a.m. Hodgkin's Disease. Drs William Dameshek and Isadore Olef Joseph H Pratt Diagnostic Hospital
 *10 a.m.-12 30 p.m. Boston Dispensary tumor clinic
 *8 p.m. William Harvey Society Beth Israel Hospital auditorium

SATURDAY FEBRUARY 10

- *9-10 a.m. Intrathoracic Cancer Drs Richard H Overholt and Reece H Betts Joseph H Pratt Diagnostic Hospital
 *10 a.m.-12 m. Medical staff rounds of the Peter Bent Brigham Hospital Conducted by Dr C Sidney Burwell

*Open to the medical profession

FURTHER STUDIES ON THE TREATMENT OF PEPTIC ULCER WITH ALUMINUM HYDROXIDE GEL*

E. STANLEY EMERY, JR., M.D.,† and ROBERT B. RUTHERFORD, M.D.‡

BOSTON

IT HAS become generally accepted that the neutralizing of gastric acidity is a helpful procedure in the treatment of peptic ulcer. For the average patient, the use of calcium carbonate and sodium bicarbonate, as originally advocated by Sippy, is very satisfactory and has the advantage of being quite inexpensive, but these powders are contraindicated for some patients because of the large intake of sodium. Patients with a lowered renal function may have difficulty in excreting the absorbed alkalis. Those with a tendency to form renal calculi may be made worse, and those who have a hypersecretion may require such large doses that an alkalosis develops before satisfactory control of the gastric acidity is obtained.

When aluminum hydroxide gel became available, it seemed as though this might be a useful addition to our treatment, because it was only slightly absorbed and had a fair neutralizing capacity, and because its astringent action might tend to decrease the secretion of acidity. Starting in the fall of 1937, we began to use aluminum hydroxide gel on a group of patients who were difficult to handle by means of the usual alkalis. By October, 1938, we¹ were able to show that the drug was successful in causing complete neutralization of the gastric juice, and in addition decreased the secretion of hydrochloric acid if given in sufficient amounts. In March, 1939, we² reported the results from treating 28 patients and were able to show that the most severe type of case can be brought under control. Having demonstrated that this drug will temporarily control severe cases, our next problem was to discover whether these patients could be satisfactorily continued on a medical treatment or would ultimately come to surgery. If the latter is true, it will save the patient time and trouble to have the operation performed as soon as possible. This paper deals

with the later course of the 28 patients on whom we have previously reported.

PRESENTATION OF DATA

As previously stated,¹ 16 of these cases represented the severest type of the disease, while 12 were classified as moderately severe. We purposely eliminated the mild cases because they will respond satisfactorily to any good medical or surgical regime. Nine of the patients were observed for only a month. Two of these were started on the treatment in anticipation of surgery, so that we might determine what effect aluminum hydroxide had on the mucous membrane. Two patients who followed the treatment for a month in the hospital failed to return for further observation in the Outdoor Department. Five returned once, were feeling perfectly well at the time and never came back. Four patients were followed for three to five months. They were all feeling well at the time they were last seen, and the gastric analyses showed a lower titration of hydrochloric acid than before starting the treatment.

This leaves 14 patients who were followed for eleven to eighteen months, with an average of fifteen months. Eight of these have had no symptoms and can be considered well. Two are classified as in satisfactory condition, they have had a return of mild symptoms on one or two occasions. The condition of 4 is unsatisfactory, 1 is dead, 1 has had a massive hemorrhage, and 2 have had a return of acute symptoms.

Those patients who fall into the "well" group took aluminum hydroxide every hour throughout the day for four or five months. After this, they were given a regime of milk once between meals and a dose of aluminum hydroxide five or six times a day, so that all have taken a maximum of six doses a day for a minimum of three months. Five cases in this group were originally classified as of the severest type, and 3 were called moderately severe.

*From the Medical Service of the Peter Bent Brigham Hospital, Boston, and the Department of Medicine, Harvard Medical School.

†Instructor in medicine, Harvard Medical School; associate in medicine, Peter Bent Brigham Hospital.

‡Assistant resident physician, Peter Bent Brigham Hospital.

Of the 2 patients who showed satisfactory results, the first had had a subtotal gastrectomy performed for a carcinoma in the pyloric region. He later developed a marginal ulcer and complained of pain, particularly at night. Aluminum hydroxide was allowed to drip into the stomach continuously for one week, following which he took the medicine at hourly intervals throughout the day. Under this regime he was completely free of all symptoms for one month. Since then he has had occasional discomfort at night, which is promptly relieved with a dose of aluminum hydroxide. At no time have his symptoms been so severe as they were before he started on aluminum hydroxide. The second patient was a woman who received the drug hourly for four months. For the next eleven months she took it six times a day, with complete relief until her child became seriously ill with pneumonia. During this period of worry and marked fatigue she stopped taking the medicine, with the result that she suffered a return of some mild symptoms. These were promptly relieved by the resumption of hourly doses of the drug. This case was originally classified as the severest type.

Of the 4 unsatisfactory cases, the first was originally classified as severe. The patient always had difficulty in taking the medicine and was unable to keep the tube down during the day, so that she was started with hourly feedings and the drip method was utilized only during the night. After a week and a half of this therapy her acid dropped from 138 to 95, but she remained on hourly feedings for only three weeks, at the end of which time she went back to the usual calcium and soda powders. A year later she re-entered the hospital with marked symptoms. A gastric analysis at this time gave a free acidity as high as 170. The patient was unwilling to try aluminum hydroxide therapy again. As we were not accomplishing anything with the ordinary alkaline powders, she was transferred to the Surgical Service. A subtotal gastrectomy was performed and she died four days postoperatively.

The second unsatisfactory case was that of a man thirty-five years old, and was classified as severe. A gastrectomy had been performed eleven months previously. A gastrojejunal ulcer developed which was not satisfactorily controlled by the ordinary alkaline therapy, and the patient was placed on aluminum hydroxide. He followed the treatment intensively for seven months, during which time he felt perfectly well. He was then transferred to six doses during the day, but at the end of seven months had a massive hemorrhage. This particular attack of bleeding followed an orgy of beer and scallops. He was then advised to take hourly doses of aluminum hydroxide, but there was some

doubt in our minds as to how thoroughly he followed any regime. At any rate, he admitted not having taken the medicine as instructed, and five months later he had another hemorrhage.

The third case was originally classified as moderately severe, and the patient was completely relieved while taking the drug hourly, which he did for the first five months. He was then transferred to six doses a day and for a period of time continued to be free of symptoms. He then developed a marked mental depression which was associated with a return of the gastric symptoms. In spite of this fact, the free acidity remained considerably lower than it was before the treatment was started. Before treatment was instituted it was 100, and seventeen months later only 52.

The fourth case was originally classified as of the severe type. The patient followed intensive treatment for two months, at the end of which time he felt well. Then for fourteen months he took the treatment in a very haphazard way, paying little attention to any advice which was given him. He was very neurotic and it was difficult to evaluate his complaints. His first gastric analysis showed a free acidity of 100, and one done only six months later was 48.

Of these patients who showed unsatisfactory results, 1 never took proper treatment, 2 were well so long as they followed treatment, and trouble developed only when they did not take reasonable care of themselves, 1 developed symptoms after the onset of a marked mental depression. The gastric acidity has been checked in the 18 cases which were followed for three to eighteen months. In 14 cases it remained lower than before the treatment was started. The average before treatment was 97, but fell to 48 at the time of the last observation.

DISCUSSION

Interest in this group of patients centers around the 14 whom we have been able to follow for an average period of fifteen months. The others have not been observed long enough to permit us to draw any worth-while conclusions. Eight patients followed for the longer period are well, 2 are in a satisfactory condition, and 4 have had unsatisfactory results. The striking fact shown by these figures is the high percentage of well patients in a group which was chosen for the severity of the disease. It is to be expected that better results will be obtained by any form of treatment on patients who are being closely followed. The very fact that the patients are cognizant of the interest being shown in their progress causes them to follow treatment more assiduously than if they were not watched so closely. On the other hand,

it must be remembered that if we had not been interested in determining what could be accomplished by the use of aluminum hydroxide, subtotal gastrectomy would have been advised for all but possibly 3 of these patients. Past experience has taught us that the usual medical treatments accomplish so little with this type of case that surgery will save time and trouble. In this connection, it is interesting that the only patient who completely failed to follow treatment ultimately came to a subtotal gastrectomy and suffered a postoperative death.

It must be emphasized that the use of aluminum hydroxide is only another way of neutralizing gastric acidity, and does not hold out any greater hope for an ultimate cure than do the other methods of antacid therapy. But it is our opinion that aluminum hydroxide is the most effective drug that we have found to date for controlling severe cases during a period of acute activity. It now appears that if special attention is given to these patients, many of them can be carried along satisfactorily on a medical regime, provided they are willing to take five or six doses of the gel a day. Also, it is our present opinion that these patients have done better by continuing on five or six doses of aluminum hydroxide than if they had reverted to the usual calcium and soda powders. This may be due to the aluminum's maintaining the gastric acidity at a lower level than if the patient had taken some other form of alkali. We say this because it is our impression that patients with similarly severe cases who have been treated by the usual alkalis and have been temporarily relieved of their difficulties have not continued to do so well as did this group of patients. However, this is mere speculation, because we are not acquainted with any data which tell us whether the severe type of case, during a period of acute activity, shows an excessively high secretion which will later drop after the acute activity has subsided.

The work of Brown and Dolhart³ suggests that there is no relation between the secretion of hydrochloric acid and the relative activity of the ulcer, but their observations do not specifically cover this type of case.

In view of the observations which we have made to date, we are inclined to give the severe type of case a trial with aluminum hydroxide before advocating subtotal gastrectomy. We say this not only because of these results, but because we have never been so enthusiastic about subtotal gastrectomy as have many other clinicians. There is always great enthusiasm for some new method of therapy, which usually decreases after a sufficient time has elapsed for a proper evaluation of results. As one of us has continuously pointed out, subtotal gastrectomy interferes with the efficiency of digestion and, by and large, patients are better off with their stomachs than without them. Although our clinic has been very conservative about the use of radical surgery, we have already had enough undesirable results to make us believe that this type of therapy should be used only as a last resort.

SUMMARY AND CONCLUSIONS

The results from the use of aluminum hydroxide therapy on 14 cases with peptic ulcer of the severe type are reported.

After these patients had been observed for an average of fifteen months, 8 were found to be well. Two others were getting along satisfactorily, although they had had a temporary return of mild symptoms, and 4 were in an unsatisfactory condition.

These results are considered very gratifying in view of the fact that all these patients were chosen for treatment because of the severity of their disease.

It is suggested that treatment with aluminum hydroxide has a definite place in the medical therapy of peptic ulcer, and that patients should be given the advantage of this therapy before subtotal gastrectomy is advocated.

OMENTUMECTOMY AS A SAFEGUARD AGAINST THE RECURRENCE OF OMENTAL ADHESIONS*

CHARLES L. LARKIN, M.D.,† AND VIRGINIA G. BURNHAM

WATERBURY, CONNECTICUT

PROBABLY the patients who cause more worry to the surgeon and suffer more chronic miseries than do any others are those who have omental, visceral, parietal or pelvic peritoneal adhesions which have been caused by peritoneal injuries

It has been my custom in cases where no acute infection was present and the omentum was found adherent to the pelvic organs, to free the omentum and remove enough of it so that the remainder was too short to reach into the pelvis, and therefore could not readhere to the pelvic organs. The patients who had omental adhesions were usually those who had had one or more previous operations or suppurative conditions such as salpingo-oöphoritis or appendicitis. The omentum was removed as the first procedure in these cases before the other lesions were taken care of. In my private practice, I have continued to cut off the omentum in such cases, but as the years have gone by, the tendency has been to remove the omental apron at a higher and higher level.

The American literature reveals no one advocating the removal of the omentum, but on the contrary lays stress on the important functions that are performed by this structure, such profound silence suggests that the procedure is so radical and would be followed by such dire results that the subject should not even be discussed.

The almost universal practice seems to be to let the omentum alone except where by its adherence it is causing definite obstructive symptoms or displacement of the organs. Under these conditions, the omentum is simply freed at the point where a dysfunction is being caused, and is then allowed to drop back into the abdomen, no attempt being made to free any more of it that may be adherent elsewhere. This procedure is still carried out, although nearly all surgeons will agree that adhesions recur in spite of all attempts that have been made up to the present time to prevent them. Their hope is that the adhesions will not again cause as severe a dysfunction as that for which they are operating, or at least that the immediate cause for operation will be relieved. They know

that any new loose connective-tissue adhesions are unlikely to cause immediate severe symptoms following operation. It is only when these adhesions become old and thickened and necessarily shortened that they give rise to kinking of the bowel, intestinal obstruction, displacement of organs, occlusion of tubes and so forth.

Surgeons throughout the years have realized the seriousness of adhesions following operations and have tried all sorts of bizarre means to prevent them. Jones and McClure¹ have enumerated the foreign substances which have been introduced into the abdominal cavity in order to prevent the contact and agglutination of injured surfaces until healing can take place. To this end innumerable solutions, gases, oils, waxes and membranes—such as oxygen, nitrogen, air, salt solution, dextrose, sodium citrate, olive oil, lanolin, gelatin, paraffin, gum arabic, silver foil, gutta-percha, Cargile membranes, amniotic fluid and silk—have been tried, and they have all produced the very thing that they were introduced to prevent. These surgeons either do not know or do not believe Hertzler's² rule: "What the peritoneum cannot absorb it walls off or dies in the attempt. Any foreign body not capable of absorption is encapsulated." They have tried all the above methods, but would not dream of touching the omentum because they have been taught certain things in regard to it which make them loath to do so any oftener than is absolutely necessary. I shall mention several of these statements that are accepted without question, and shall attempt to prove that they are not pertinent.

Jones and McClure¹ state

The regularity with which the omentum is found attached about diseased foci with more or less complete walling off or isolation of the process has earned for it such striking designations as "the policeman of the abdomen" and "the abdominal leukocyte," and much has been written about its almost intelligent migratory powers.

That the omentum has the intrinsic ability at a moment's notice to rush to the site of an acute infection and wall it off is quite fantastic. Florey and Carleton³ have shown that the movement of the omentum is entirely extrinsic. The factors influencing its change in position are

*Read at the annual meeting of the New England Surgical Society, Salem, Massachusetts, September 29, 1939.

†Attending gynecologist, Waterbury Hospital and St. Mary's Hospital, Waterbury, Connecticut.

posture, gastrointestinal peristalsis and diaphragmatic excursions. If one of these factors does not happen to bring the omentum to the site of infection, or, as is often the case, the omentum is too short to reach the focus, the intestines themselves will be forced to perform the function of walling off, and usually do.

Jones and McClure claim that the removal of the omentum is very likely to be followed by acute generalized peritonitis if the patient happens at a later date to develop a suppurative focus of infection and the omentum is not present to wall it off. I believe that the omentum plays a part in walling off areas of disease and foci of infection and often prevents generalized peritonitis, but this does not necessarily mean that the visceral peritoneum could not perform that function just as satisfactorily if the omentum were not present. It has been estimated that the total peritoneal surface area is equal to the total skin area. The peritoneal covering of the omentum makes up only a small percentage of this surface. The parietal and visceral portions of the peritoneum remaining after the removal of the omental apron have the same physiologic absorptive properties as that covering the omentum, and will respond in just the same way to infection and irritation, causing serous exudation, a pouring out of leukocytes and fibrin formation, and the contiguous inflamed or irritated intestinal surfaces will adhere and wall off the infection in the same manner as does the omentum.

Jones and McClure also state that the omentum with its characteristic cells having distinct evolutionary history and function, is to be regarded as a parenchymatous structure analogous in some respects to the thymus gland and the bone marrow, they therefore believe that if the omentum is removed certain disease fighting enzymes or cells will be lacking to combat any future suppurative foci of infection. Modern pathologists⁴ contend that the peritoneal cells covering the omentum do not have these analogous functions.

Graves⁵ points out that the omentum is covered with two layers of peritoneum, one on each side, and that it is well supplied with blood and lymph vessels, which furnish a greater amount of serum and phagocytes than does the rest of the peritoneum. This is undoubtedly true, but the visceral and parietal portions of the peritoneum have enough of these properties so that they are able to glue themselves together and surround foci of infection when they are called upon to do so. This author also states that it has been shown by experiments that animals from which the omentum has been radically removed

are less resistant to peritoneal infection than are normal control animals. This may be so, but medical and surgical literature does not reveal that human subjects having little or no greater omentum have an increased susceptibility to peritoneal disease, and none of the patients from whom I have removed the omentum have developed peritonitis. The two commonest sources of suppuration in the abdominal cavity are the appendix and the fallopian tubes, and these have usually been removed at the first or a later operation. If this is not the case, the appendix should be removed and all pelvic disease corrected at the time of omentectomy. Therefore, the danger of generalized peritonitis occurring at some future date is only remote.

Graves adds that the omentum can be used to cover denuded and injured peritoneal surfaces. This is the exact process we wish to avoid, for these adhesions cause chronic invalidism, which fact has been evidenced by the number of cases that have to be operated on again and again. He also states that it takes two injured contiguous surfaces to cause adhesions between one organ and another. This being so, it is an unquestioned fact that if the adhered omentum is freed and again dropped back into the abdominal cavity it is bound to readhere, because, first, it is a relatively immobile structure and will return by force of gravity and by the factors that influence its movements to its normal position, and secondly, the injured omental surface which was freed will very likely again be in apposition to the injured peritoneal area from which it was freed, thus the adhesion will again occur, according to Graves's statement that two injured contiguous surfaces in close apposition to one another will unite. Graves apparently did not realize the importance of his statement, for he did not utilize it in order to combat adhesions. The significant words are "two and contiguous." This means that if two injured surfaces are separated and kept so, or if one of them is eliminated, adhesions will not recur. The rationale of removing the omentum in order to prevent adhesions is based on these two facts. If the omentum is cut off high enough so that it cannot reach the area from which it was freed, there will be no readherence, also no adhesion will occur in the pelvis, because the raw surface there will come into contact only with the normal visceral peritoneum, which is well lubricated by serous secretion, the intestinal loops, slipping by one another and moving from place to place, will not as a rule be in contact with a mildly irritated surface long enough to unite with it.

Graves also points out that the omentum slips

into hernial openings and prevents the entrance of bowel. It is also considered a storehouse for fat, and undoubtedly acts as a blanket for the intestines and prevents their sudden chilling. These functions may well have been important in the Stone Age, but they are of little significance in the modern era of superheated homes and warm clothing.

When I perform pelvic operations, I open the abdomen by a midline incision from the umbilicus to the pubis (Fig 1). The adherent omentum is dissected free by cutting the weblike or fibrous con-

splenic flexure, after each blood vessel that is visualized has been sutured. As soon as the heavy, redundant omental apron is removed, the whole colon, relieved of this weight, has a tendency to be drawn into the upper abdomen above the umbilicus by the shortened greater omentum, which runs directly from the greater curvature of the stomach to the upper border of the transverse colon. Consequently, there is no longer a fat pad covered with serous membrane between the small intestine and the parietal peritoneum. This leaves a thin, raw area, about 0.3 cm thick, stretching

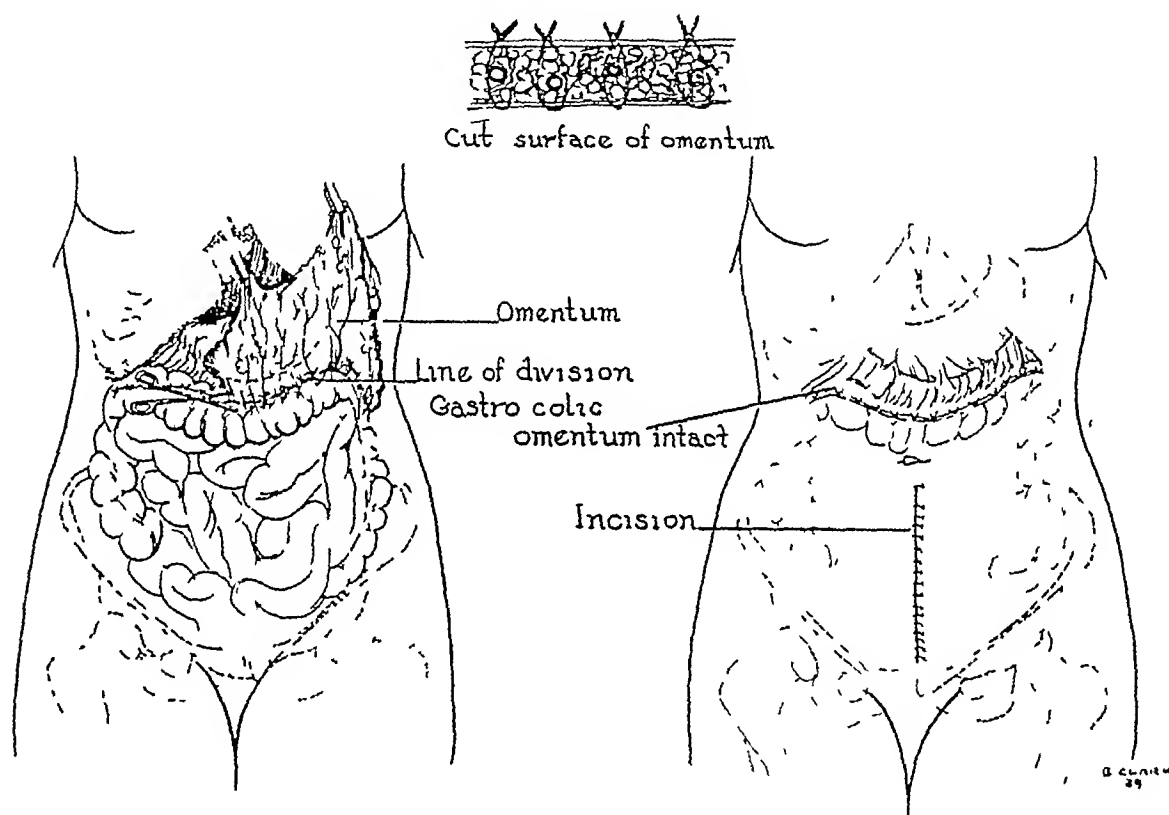

FIGURE 1

nective tissue that attaches it to the peritoneum. This leaves simply the peritoneal surface covered with serous cells and an overlying, practically bloodless, thin veil of cobwebby or somewhat fibrous connective tissue. This tissue has a very poor blood and lymph supply, and when cut produces slight exudation of blood and lymph, which is necessary for the formation of fibrin, there is therefore little tendency to adhere or readhere. Traction is next placed on the freed omentum, and it is pulled through the incisional wound. When it is pulled upward, the transverse colon is visualized and the attachment of the omentum to its superior border is noted. A suture is placed through the border of the omentum at the hepatic flexure, and the omentum is cut through just distal to the tie. The excision is continued along the upper border of the transverse colon to the

along the whole superior border of the transverse colon. The outer and inner surfaces of this incised area consist of a thin layer of epithelial cells, and in between are fat tissue and a lacework of connective tissue; there is no injured parietal peritoneal surface in the upper abdomen to which the cut edges of the incisional wound can adhere. As a matter of fact, the cut edges naturally adhere to one another, being contiguous and raw. The injured parietal peritoneum in the pelvis comes into contact only with the visceral peritoneum, and the viscera, continually changing position, do not stay in one place long enough to adhere unless the peristaltic waves have been temporarily stopped because of shock.

Graves states: "The chief function of the peritoneum is to secrete enough serous fluid to lubricate its highly polished serous lining so that the

stomach and intestines are free to move around in the abdominal cavity with the greatest of ease, and so that there is no interference of the normal peristaltic movements of these organs." These movements are necessary for the proper digestion of food and the elimination of waste products, and if the omentum is drawn down into the pelvis it is bound to cause continuous pulling and kinking of the transverse colon and stomach. By compression it also interferes with the peristaltic movements of the small intestine, thus preventing the normal digestion of food and the elimination of waste products, and giving rise to all sorts of gastric symptoms, such as fullness, gaseous eructations, pain, distention and constipation.

There are other factors which must be complied with if postoperative adhesions are to be prevented

Normally there are a few cubic centimeters of excess serous fluid in the abdominal cavity. But if a patient is debilitated or dehydrated there is less than normal serous exudation on the surface of the peritoneum, and therefore less lubrication and conversely more friction. If such a peritoneal surface is handled at operation, its delicate covering of relatively dry endothelial cells is more easily injured and it more readily adheres to another area. Therefore it is well to combat dehydration before operation by forcing fluids, and to institute routine intravenous therapy postoperatively for at least three days until the patient is again taking plenty of fluids by mouth.

The patient should be anesthetized so that there is complete abdominal relaxation and deflation of the viscera. A basic Avertin anesthesia, supplemented by ether, or a spinal anesthesia with novocain and Pontocaine gives the relaxation that is needed if the adhesions are to be easily dissected free without causing trauma and later, adhesions.

Finger dissection and forcible separation of adhesions by traction should never be done. Such a procedure results in more raw surfaces and thus defeats the purpose of the operation. Only the redundant part of the omentum which is to be removed should be touched by instruments or by the hand.

If the anesthesia is satisfactory, there is little or no need of walling off the viscera by the insertion of packing tapes or heavy retractors, which may in themselves cause trauma to the delicate peritoneal cells.

If clamps have to be used on the cut edges of the peritoneal incision they should be placed on the very edge, and when the peritoneum is closed these areas, traumatized by clamps, should

be turned outward, leaving no injured areas along the line of suture to which the intestines may adhere.

After any complete anesthesia there is a period when the intestinal tone is entirely lost and when there are no peristaltic waves passing along the intestinal tract, thus there is very little slipping around of the loops of intestine except that caused by diaphragmatic excursions. It is during this postoperative period that the patient must be moved from side to side so as to ensure movement of the coils of intestines by change of position.

In view of the dire results that have been prophesied should the omentum be removed, the case histories of the 76 patients from whom I have removed in the last seventeen years either all or a large part of the omentum have been reviewed in order to ascertain just what good or bad results have followed. Sixty five patients had had previous operations and most of these had subsequently been suffering from chronic gastric disturbances. Forty-one patients had had one operation, 12 two, 11 three and 1 four.

Following omentectomy, 11 of the 76 patients had a subsequent operation. These case reports are briefly as follows:

CASE 1. D. F. had an operation for peritonitis, then an appendectomy and omentectomy for adhesions. After this she had an ectopic pregnancy and a few light adhesions were found. She has been well since then.

CASE 2. B. K. had an appendectomy then a fibroidectomy, an omentectomy and a suspension operation. Later she had persistency of chronic metritis and underwent a hysterectomy. No adhesions were found.

CASE 3. A. S. had a salpingo-oophorectomy then a colpotomy for pelvic abscess, then a hysterectomy and then an operation for intestinal obstruction with omentectomy for adhesions. Later a laparotomy was performed for symptoms simulating intestinal obstruction but she was evidently suffering from hysteria since no adhesions were found, and the abdomen was sewed up without any abdominal manipulations. The patient has been well since then.

CASE 4. D. C. had a salpingo-oophorectomy and appendectomy then a hysterectomy and then a laparotomy and an omentectomy for adhesions. One subsequent laparotomy was performed in order to free visceral adhesions. The patient has been well since then.

CASE 5. M. B. had had an oophorectomy and appendectomy before I performed a hysterectomy for fibroids and omentectomy. Since then she has had two operations in a neighboring town the types of which are unknown.

CASE 6. E. K. had had an appendectomy before I performed a hysterectomy for fibroids and removed the omentum. Following this she had a cholecystectomy. Adhesions were found in the region of the gall bladder. Since then she has been well.

CASE 7. M. F. had an appendectomy and then a left salpingo-oophorectomy and omentectomy. Following

this she had a hysterectomy, very few adhesions were found. She has been well since then.

CASE 8 J K had had an appendectomy and suspension before I performed a left salpingo-oöphorectomy and omentumectomy. Later she had a hysterectomy for pelvic symptoms, a few adhesions were found.

CASE 9 M R had had an appendectomy, then a hernial repair and oöphorectomy, and then gall bladder drainage. I did a hysterectomy for fibroids, found adhesions and removed the omentum. Subsequently the patient had a cholecystectomy, there were a few adhesions in the gall bladder region, but none in the lower pelvis.

CASE 10 H S had had no previous operation until I performed a suspension and removed part of the omentum. Later she had a cholecystectomy for cholelithiasis, no adhesions were noted.

CASE 11 G M had had an appendectomy before I performed a left salpingo-oöphorectomy, suspension and myomectomy and removed most of the omentum. She later had an operation by another surgeon, but no report is available.

Except for Cases 5 and 11, concerning which information is lacking, it can be said that none of the 76 patients have had to undergo a subsequent laparotomy because of any complication arising from the removal of the omentum. All patients are alive except 4 who had cancer at the time of operation and had their omenta removed on account of metastases. No intestinal obstruction has occurred. No acute infection has arisen. Apparently the adhesions present at the time of operation have not re-formed to a sufficient extent to warrant further operation, with one exception (Case 4).

It would be incorrect to say that these patients have no gastric and abdominal complaints, but our follow-up shows that they are all enjoying fairly good health considering their previous chronic invalidism. Forty-four patients have reported complete relief from their gastric and abdominal symptoms, 18 partial relief and 3 no relief. Four died from carcinoma, 7 have moved away and reports have not been obtainable.

SUMMARY

Omental adhesions cause distressing gastrointestinal symptoms and chronic invalidism.

Up to the present time no satisfactory method has been proposed that would prevent the re-adherence of the omentum.

Removal of the omentum is suggested as a fairly satisfactory method for treatment of omental adhesions after they have once occurred.

Case histories are cited to prove that no serious complications have followed omentumectomy.

Omentumectomy was only one portion of the operative procedure, and therefore all the good results following these operations cannot be at-

tributed to the removal of the omentum per se, but at least it enhanced rather than lessened the patients' chances of future good health.

DISCUSSION

DR GEORGE M. WATERMAN, Providence, Rhode Island. I have never encountered the total removal of the greater omentum. Dr Larkin has given a good deal of thought to this subject, and has covered the ground and presented his argument very well. This procedure seems rather radical, however, I have had no experience with it, and Dr Larkin has. His results, he thinks, are very good. He believes that he has had no more recurrence of adhesions, or postoperative discomfort or complications, than have surgeons who do not practice this procedure. On the other hand, he has not reported any control series which would show whether or not his argument is sound.

Personally, I shall continue to believe in the value of the great omentum, and shall be loath to remove a structure which I have always thought was a protection. This is a matter that deserves our consideration, and one concerning which we may possibly change our opinions.

DR. JOHN ROCK, Boston. I have had, unfortunately or not, no experience in the removal of the great omentum. I have, to be sure, at odd times removed a fair-sized portion of the omentum when, in separating adhesions from pelvic tumors, I had mutilated a large part of it or interfered with its blood supply. I have also removed part of it without dissecting it free from, perhaps, a fibroid, to the circulation of which it was possibly contributing a major part. More often I have used it to cover injured areas after dissection for pelvic tumor.

I think we can all agree with Dr Larkin's very inclusive enumeration of the physiological properties of the omentum, and can agree with him that in order to exercise its function it does not have to be mobile. This is unlike the similar physiological functions of the peritoneum which covers the intestines. Dr Larkin has also emphasized the figurative terms which have been applied to the omentum, "the policeman of the abdomen" and "the abdominal leukocyte." I must confess that I still believe these terms to be justifiable.

I have not had much to do with general surgical complications such as ruptured gall bladder or perforating ulcer, but if I had, I should hope that the omentum would be present, and I know that if ever my appendix should rupture, or that of any of my friends, — and I use the word in the Rooseveltian sense, — I should hope that the omentum would be at hand.

DR JOE V MEIGS, Boston. My only experience in this matter was with one of Dr Larkin's own patients. In this case I found inside the abdomen a large, thick, smooth border of omentum that was high up. The patient was absolutely free of all adhesions, and had a perfectly

smooth omentum not over 8 cm. in length at any point. I can only offer this observation for what it is worth.

DR. DAVID CHIERVIZ Boston I will be frank in expressing doubts about Dr Larkin's thesis. I have always considered the omentum a somewhat unaccountable but very useful structure, and having all my life preserved it so far as I could, I am not very much inclined to give up this practice. I call Dr Larkin's attention to the fact that almost invariably when one operates on the abdomen of a person previously operated on, one finds the omentum adherent to the deep surface of the abdominal wound the adhesion rarely in my experience, causes any obstruc-

tion. I have always thought that this adhesion was a useful lesion and that it probably prevented the adherence of the intestine to the wound which in turn might prevent normal peristalsis. My own belief is that unless the changes in the omentum are such as to indicate its removal, it should be preserved.

DR. LARKIN (closing) I agree that it is well not to be too hasty in taking up new procedures and discarding the old. But when the old procedure causes the chronic invalidism that so often follows omental adhesions I believe it is time to try omentectomy which in my hands at least, has tended to prevent crippling adhesions.

THE PROGNOSIS OF INFANTILE TUBERCULOSIS*

CLEMENT A. SMITH, M.D.,† AND WINIFRED DE LACEY‡

BOSTON

IN a recent study¹ of 345 deaths from tuberculosis at the Infants and Children's hospitals, the factor of age assumed outstanding importance. A high mortality was demonstrated in the first two years of life, as compared with a very low level in older childhood. Moreover, a significant difference in the pathologic lesions at different age levels was also apparent, deaths in infancy being usually the terminal event of milary tuberculosis, while those of older children were much more commonly due to tuberculous meningitis not associated with milary disease. In general, these findings have been observed by many other workers and were to be anticipated, but they increased our interest in the significance of the earliest years of life as the most valuable period for pediatric efforts against tuberculosis mortality. The importance of infancy, in contrast particularly with the later grade school period is shown by Table I with its 200 deaths in the first two years studied and its 6 deaths in the last two. In spite of the decrease in mortality during the period studied, the table shows how constantly the problem has been centered in infancy.

A natural outcome of the concentration of interest on infantile tuberculosis has been curiosity as to the fate of those tuberculous patients discharged from the Infants Hospital during a period of years comparable to that covered by the mortality study. In the fifteen year period from the beginning of 1924 to the end of 1938, 339 infants with some form of tuberculosis were seen in the hospital, and of this number 191 (56 per cent) died there. Data from their records form part of the preceding study. The present communi-

cation is based on a follow-up study of the remaining 148 infants who did not succumb to tuberculosis during their first hospital admission.

In almost all these infants there was roentgenological evidence of disease in the lungs or medi-

astinal lymph nodes, but patients with tuberculous peritonitis, cervical adenitis or bone lesions were included in the present study if they also showed evidence of tuberculosis in the thorax. Three tuberculin-positive infants with negative roentgenograms were also included, on the ground that their infection could hardly be entirely healed or inactive. In 32 cases no satisfactory data as to the course of the patient after discharge could be obtained their omission brought the total number of records available for study down to 116. These infants were traced by letters and home visits to parents, by reports from other hospitals, sanatoriums and tuberculosis clinics, and by reference to our own records on those patients now attending the clinic. Since our first interest was in the survival of these children, we have not yet attempted to have them all

brought back for re-examination and roentgenograms. Indeed, the impression resulting from this and similar work in other clinics suggests that the present roentgenological status of children who have now reached the low-mortality ages of later childhood would be mainly of academic interest.

An early impression which was confirmed by the results of this investigation was that subsequent deaths from tuberculosis in the later life

the surviving and non-surviving patients are included, and show a slightly older age at diagnosis for infants whose course was favorable. Table 3 presents the length of known survival after the disease had been discovered, and brings out again the short period between diagnosis and a fatal termination, when that occurred.

The more important roentgenological findings at admission are shown in Table 4. Here the fatal cases are limited to those which did not have

*Nineteen patients had miliary or meningal tuberculosis on admission.

of these infants occur almost always within a year's time. In fact, in only 1 of 42 infants who succumbed after leaving the hospital did death occur more than twelve months after the diagnosis was made. This patient lived only eighteen months. Because of this critical significance of the first year after diagnosis, we have included in our statistics the records of 22 infants whose present status is undiscoverable but who were traced and in apparently good health.

evidence of meningitis when the patients first came to the hospital. In some cases a patient was listed in more than one of these classifications, as when there were coexistent enlarged soft shadows and calcification at the hilus. By diffuse congestion is meant the frequently observed and poorly circumscribed patchy or mottled shadows suggesting the appearance of bronchopneumonia. In no case have such findings been included unless their persistence in repeated films

*Omits 5 patients who later died of nontuberculous causes.

at least one year after being at the hospital. More than half these children had survived over five years before they were lost from the records. Since there seems to be so little evidence from the known fatalities that such patients went on to death from tuberculosis thereafter, it seemed reasonable to use them for drawing certain of our conclusions.

Data have been arranged in several tables, on which brief comment may be made. Table 2 presents a general summary, the average ages of

indicated their specific etiology. It will be observed from Table 4 that 1 infant with what was assumed to be miliary disease survived, and that no patients with calcification when first seen later died of the disease. Moreover, the 3 infants with positive tuberculin tests but negative roentgenograms were all in the group with a favorable outcome.

No tabulation of later exacerbations of tuberculosis in the group of survivors is presented, nor have we exact enough data to enable us to

discuss the difficult question of the activity or healing of their earlier infections at the present time. It is known, however, that 6 of the survivors developed foci which persist at the present time. These include 1 child who now has tuberculous cervical adenitis, 2 with cervical adenitis and skeletal tuberculosis and 2 with skeletal lesions only. The sixth and most interesting child has apparently developed a reinfection or adult-type lesion in the lungs. This patient was seen in the hospital in 1924 at the age of seven months, with

physical and roentgenological signs of dense consolidation throughout the left upper lobe, a result of intimate contact with a tuberculous mother. She spent the next two years at a sanatorium for tuberculous children, and was discharged at the age of three with regression of the lesion and the appearance of calcification. After two admissions to other institutions, mainly because of poor home conditions, the child was found at the age of fourteen to have developed a soft subapical shadow on the left, for which she was again hospitalized as having minimal adult-type tuberculosis. She has remained sputum negative, but artificial pneumothorax has had to be abandoned because of old pleural adhesions.

COMMENT

The fate of the tuberculin-positive infant has been the subject of a number of recent communications in the literature, a few of which may be briefly reviewed before making general comment on the present series.

Briley⁷ in 1936 published observations on 170 infants studied at the Harriet Lane Home in Baltimore. Somewhat more than half these patients were colored. The maximum period of observation was five years, and the material was tabulated with particular reference to the presence or absence of lesions demonstrable by roentgenogram at first admission, and to the presence of sputum-positive contacts. Sixty-seven patients had a parenchymal lesion at first examination, 36 had bulging tracheobronchial nodes and 67 had negative chest x ray films, the mortality within

these three groups was 40 per cent, 13 per cent and 9 per cent respectively. Approximately 70 per cent of all deaths occurred during the first year following the discovery of the infection. The total five year mortality for the colored children was 31 per cent, as against 13 per cent for the white children.

As a part of Rosenberg and Kereszturi's⁸ investigation of BCG in New York City, a group of non vaccinated infected infants was observed for one to nine years. They report a death rate of 9 per cent for 348 infants followed. In the majority of cases in which roentgenograms were made, no evidence of tuberculosis was found, so that their group represents, even more than does Brayleys, a milder degree of infection than was present in our patients. All the 32 fatalities in their series occurred by the end of three years, and more than half of these during the first year. Tortone and his associates⁹ have recently reported on the course of 209 infants reacting to tuberculin at the Lymanhurst Health Center. In a follow up period averaging five years there were 10 deaths from the disease. Again, a large proportion of these patients were roentgenologically negative.

A very extensive study by Söderling¹⁰ is based on 912 tuberculous infants observed at three hospitals in Stockholm during a period of twenty-five years. Of this large series, 487 died of their disease within three years after its discovery, 90 per cent of the deaths occurring within the first year. During the same period 13 patients succumbed to nontuberculous infections. Of the 412 surviving patients, 405 were followed for periods varying from five to twenty five years, a record which arouses the envy of anyone who tries to trace the later course of even a hundred infants. It was discovered that only three of the 405 patients succumbed to tuberculosis during this period. In view of his observations, Söderling suggests that a considerable degree of immunity had been established by the infection in infancy.

Such statistics as those reviewed above demonstrate wide variations in prognosis, depending on the degree of involvement at the time the infection is discovered. The most satisfactory results are those from institutions whose work is largely case finding in nature. In the earlier years of the present study, the majority of tuberculous infants died during their first admission of miliary or meningeal tuberculosis—conditions already present in most of them at entry. Those discharged alive usually represented cases of advanced disease, so that few were expected to survive. In more recent years it has been possible to discover and admit more infants in earlier stages of infec-

tion A smaller proportion of such patients have died in the hospital, moreover, more of those discharged alive are surviving

From all studies, including our own, it seems fairly certain that tuberculous processes in infancy run a comparatively acute course Once an infected infant has survived a year—or perhaps two years—after the discovery of his disease, his prognosis becomes reasonably favorable and a relaxation of care and observation is permissible It is obvious from all the references that infection beginning in the earlier months of infancy terminates in a higher percentage of fatalities than that which arises nearer the age of two years It is also apparent that the outlook for the tuber-

groups Important alliances can be made between pediatric clinics and obstetric hospitals, so that the newborn infants of tuberculous parents can be regularly tested for infection during the dangerous years To await the development of symptoms in infants before looking for tuberculosis is an even graver error than it is in adult patients Too often the appearance of symptoms is the outward evidence that an irreversible pathologic process has begun Responsibility for diagnosis before the onset of this phase rests on the physician and the clinic The means of diagnosis are the family history, the tuberculin test and the roentgenogram The results of such efforts should be not only an ultimate diminution in the number of

TABLE 5 Comparison of Results in the Three Five-Year Periods

| RESULTS | PERIODS OF ADMISSION | | |
|-------------------------------------|----------------------|-----------|-----------|
| | 1924-1929 | 1929-1934 | 1934-1939 |
| Total tuberculous patients | 173 | 100 | 66 |
| Died in hospital | 106 (61%) | 56 (56%) | 29 (44%) |
| Living at discharge | 67 | 44 | 37 |
| Untraced | 24 | 6 | 2 |
| Traced | 43 | 38 | 35 |
| Died after discharge | 17 | 16 | 9 |
| Died of nontuberculous disease | 3 | 1 | 1 |
| Survived for over 1 yr | 23 (54%) | 21 (55%) | 23* (66%) |
| One year survivors | 13% | 21% | 35% |
| Total mortality due to tuberculosis | 71% | 72% | 58% |

*Actually 25 survivors but 2 have not completed the full year

culin-positive infant can be made more favorable than it once was This is demonstrated by a division of the fifteen-year period of the present study into three periods of five years each, as shown in Table 5 It is gratifying to note that the percentage of tuberculous babies surviving for a year after discovery was more than twice as great for the last as for the first five years studied However, even in the last period nearly half the tuberculous infants brought to the hospital died shortly following their first and only admission Death often occurred only a few days after entrance, at which time the disease was usually present in a miliary or meningeal phase

Thus, whatever improvement can be shown for prognosis is largely the effect of earlier diagnosis rather than of better therapy The line of successful attack against tuberculosis as a pediatric problem is clearly indicated The excellent results from Lymanhurst and from New York City demonstrate how much can be done by methods which seek out infected infants by case-finding methods before those patients would ordinarily be brought to a hospital for sick children Children's hospitals and clinics, and private practitioners as well, should seek out the infant siblings of tuberculin-positive older children, instead of concentrating so much time and attention on those in safer age

tuberculous infants, but also a better prognosis for those discovered

SUMMARY AND CONCLUSIONS

Since the great majority of deaths from tuberculosis during infancy and childhood occur in the first two years of life, the attention of pediatricians must be centered on infancy as the most important age period for further lowering the mortality from this disease A study of the outcome of tuberculosis in 339 infants over a period of fifteen years has demonstrated a 56 per cent mortality for the group during the first admission to the hospital Of the 116 remaining patients whose course is known since discharge to other institutions or to their homes, more than half have survived for one to fifteen years after the original diagnosis was made In all but 1 of those who succumbed to their disease this event occurred within twelve months, 1 infant died after eighteen months Five later developed a skeletal or glandular tuberculosis, and 1 an adult type of pulmonary tuberculosis

A review of other reports in the literature indicates a wide variation in the prognosis for the tuberculous baby The mortality varies directly in proportion to the degree of disease evident at discovery In the present study almost all in

infants had roentgenologically significant disease at that time, but efforts directed toward earlier recognition of infection in recent years have been rewarded by a significant increase in the number of survivors. Such efforts must be made by private physicians, clinics and other institutions aware of the value of diagnosis by family history, tuberculin testing and roentgenography before symptoms appear.

Attention is called to the acute nature of infantile tuberculosis, and to the attendant improve-

ment in prognosis once the infant has survived the critical year after discovery.

GANGRENE OF THE SCROTUM AND REPAIR BY A SIMPLE PLASTIC OPERATION*

Report of a Case

HERBERT H. HOWARD M.D.†

BOSTON

IT IS not the purpose of this paper to discuss in detail the various types of gangrene of the scrotum, but simply to give a brief outline of the various methods, to report a case and its preoperative treatment, and to describe a simple plastic operation.

Gangrene of the scrotum may be classified under two headings.¹ To the first belongs secondary gangrene following infectious diseases, such as diabetes, the terminal stages of gangrene following some total pathologic change, such as abscess and cavernositis, and cases of mechanical origin due to chemicals, excessive heat or frostbites. To the second group belong the so-called "idiopathic" or spontaneous types of gangrene known as streptococcal gangrene and gangrenous erysipelas. As regards the latter group, there can now be little doubt as to the infectious nature of the condition. We know that there is a gangrene produced by gas-forming organisms, as well as the cases of streptococcal gangrene. It is my belief that the term "idiopathic" is rather loosely applied, and that such cases are for the most part examples of symbiotic gangrene.

The case here presented falls into the last named group. The early pathologic changes are striking, with a close resemblance to erysipelas. There is sudden acute inflammation at the onset. The skin becomes reddened, tense and glossy, and there is usually no evident portal of entry for the organisms. Campbell² states that the mode of entry is unknown, but that it is assumed that the organisms are rubbed in by friction of the clothing.

There may have been some abrasion to the skin or urethra, unknown to the patient. The surface readily pits on pressure, with the appearance of an exudate and desquamation of the dependent parts. Following this, the gangrene may spread rapidly in all directions. A line of demarcation may soon appear, or the gangrene may spread to the groin or even upward to the umbilicus or axilla. Extension usually follows the fascial planes of Scarpa and Colles. If untreated, the slough soon separates, usually in two or three days, and comes away as a foul smelling mass, leaving the testicles and penis relatively free of involvement. However, as was noted in the present case, there is frequently exposure of vessels, with the subsequent danger of hemorrhage. With proper care, improvement may immediately be noted, with rapid granulation and in time even complete regeneration of the scrotum.

The general methods of treating cases of scrotal gangrene have for the most part been fairly satisfactory. Wide excision of the involved skin and subcutaneous tissues, with continuous postoperative hot dressings of a 1:5000 solution of potassium permanganate, has seemed to work very well in many cases.

Just how important a part antistreptococcus serum may play in the treatment of some of these gangrenes, I am as yet unable to state, and the same holds true for the use of sulfanilamide. I think that at the present time by far the most effective drug to be used in cleaning up the infection is zinc peroxide.

The active treatment with zinc peroxide should not be started until the determination of the bacteriological flora of the wound has been reported.

*Presented at a meeting of the New England Branch of the American Urological Association, Boston, April 20, 1939.
†Urologist-in-charge for urology, Boston City Hospital.

This type of treatment should be used only when the organisms which are found are known to be susceptible to peroxides, such organisms include the anaerobes, the microaerophiles and certain aerobes, including the ordinary hemolytic streptococcus. It is a well-established fact that certain of the so called anaerobes are strictly anaerobic in their cultural requirement, while others seem to be in an intermediary group, growing under a slightly reduced oxygen tension and later adapting themselves to aerobic cultivation. These bacteria have been referred to as microaerophilic.³ Frequently it is possible to make a clinical diagnosis of anaerobic infections. However, anaerobic methods of bacterial cultivation are obviously necessary for accurate determination of the nature of the infection.

When the presence of these organisms has become established, there must be a preliminary surgical procedure which will render it possible to apply medication directly to the affected tissue in such fashion that the main focus will be removed, and the material then have access to the residual infection.

Zinc peroxide has been used also as a prophylactic in surgical wounds, where contamination with anaerobic and microaerophilic organisms is suspected. The prophylactic use of the drug is more logical than is its use for active treatment, as the organisms have not yet invaded the tissues. While treating active infections, zinc peroxide must be applied to every part of the wound surface, because its action does not extend far from the point of local application, as has been demonstrated *in vitro*.

The work of Meleney and Johnson⁴ indicates that the liberation of oxygen and production of hydrogen peroxide depend on the presence of water. They therefore suggest that the zinc peroxide be applied suspended in sterile distilled water, with the dressing sealed in order to prevent evaporation.

Zinc peroxide is finely divided white powder, having the consistence of chalk or talcum. It must be heated at 130 to 140°C from one to four hours in order to sterilize it and to mobilize the oxygen. For use it is mixed with roughly ten parts by weight of distilled water⁵, this is accomplished by means of a sterile glass syringe, the result being an even, creamy suspension. More water may have to be added during the dressing.

The mixture is injected from the syringe so that it comes in contact with every point of the infected surface, especially beneath the undermined skin and down into the sinuses, using a small catheter when necessary. Where the zinc

peroxide does not reach the organisms, they will continue to grow. Strips of gauze or silk are dipped in the suspension and introduced under the skin edges until the wound is completely covered, including the edges of the normal surrounding tissue. The dressing is then sealed with a double layer of vaselized gauze on zinc-oxide-impregnated gauze. The dressing should be changed daily and the old zinc peroxide washed away with sterile water or saline solution.

In the case about to be reported, there was a very marked improvement at the end of three days. The exudate decreased, and granulations appeared and became very firm. At the same time extension of the infection stopped abruptly, and

FIGURE 1 Preoperative Lesion

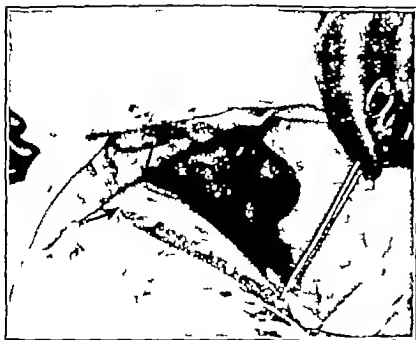

This photograph was taken 24 hours prior to operation on the day the zinc peroxide dressings were discontinued

the undermined edges were sealed off almost overnight. There were, however, a few areas which persisted for several days, appearing as whitish-gray patches associated with discharge but these responded well to treatment in a very short time (Fig 1).

CASE REPORT

J D, a 48-year-old, Italian-born cook, was admitted to the Boston City Hospital on April 13, 1938, complaining of pain, redness and swelling of the scrotum of 3 days' duration. He stated that he had noticed a swollen, non-tender "pimple" on his scrotum intermittently for several years. However, this had given him no trouble until 3 days prior to entry, when, while working over a hot stove, he noticed a burning sensation in the scrotum and began to feel weak and sick. That evening he discovered that the scrotum was red and tender. He was seen by his physician, who advised the application of icebags, and, as the condition became more severe, referred the patient to the hospital. The past history was essentially negative. The patient had had one attack of hematuria 8 years previously. He had had gonorrhea in 1917.

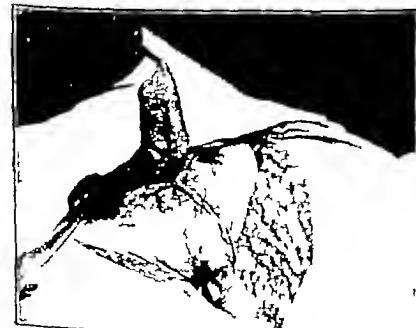

Physical examination revealed a robust, healthy-appearing man with marked dental sepsis. The general examination

was otherwise negative. Locally the scrotum was edematous and hyperemic, with a denuded area approximately 6 cm in diameter, around which there was an area of necrotic tissue with surrounding inflammation. The entire involved area was moderately tender.

Laboratory examination showed an alkaline urine containing no sugar or albumin. The sediment was free of cellular elements at all times. The hemoglobin was 65 per cent, the red-cell count 5,370,000 and the white-cell count 14,000, with 75 per cent polymorphonuclear neutrophils, 17 per cent lymphocytes, 3 per cent eosinophils, 3 per cent monocytes and 2 per cent basophils. A blood Hinton test was negative. The blood nonprotein nitrogen was 35 mg per 100 cc. The fasting blood sugar was 132 mg per 100 cc.

On admission a diagnosis of gangrene of the scrotum was made and the scrotum was immediately incised in several places. Chlorinate dressings were applied, however, the necrotic tissue continued to increase. There was no evidence of urinary extravasation. On the 4th hospital day the entire scrotum was involved and the process had started to spread to the thighs and abdominal wall. A culture was taken at this time. A complete debridement was then done, removing the gangrenous tissue completely to the line of demarcation, which extended from the base of the penis anteriorly to the anus and posteriorly and laterally to both thighs. The testicles were entirely denuded and seemed to be involved by the gangrenous process. However, they were left intact. A zinc peroxide dressing was applied, following the prescribed method.

Three days later the culture was reported positive for a hemolytic streptococcus with anaerobic properties and for *Staphylococcus aureus*. The white-cell count had dropped to 9400. The area was remarkably clean, and the foul odor had disappeared. There was early evidence of granulation and no further spread of the gangrene. However, daily zinc peroxide applications were continued in order to ensure destruction of all organisms and to promote granulation. The underlying margins gradually became sealed off, with signs of epithelization. Two weeks after the debridement the area was completely covered by fresh and healthy granulation tissue and was free of organisms by culture.

Twenty-eight days after debridement there was but little evidence that the scrotum would regenerate. A plastic operation was done, at which time two large pedicle flaps were freed from the inner surface of the thighs, the bases of which were just below the inguinal line, ensuring good blood supply (Figs 2 and 3). These flaps were so formed that they were turned over the testicles, completely covering them and forming a sac (Fig 4). The edges were approximated by the use of silkworm gut stay sutures, reinforced by skin clips. The sac was drained with rubber tissue. The denuded area left by the formation of the flaps was completely closed at this time, this being possible because of the loose skin associated with loss of weight by the patient (Fig 5). Two gauze drains were placed under each pedicle and a snug, dry sterile dressing was applied. A Foley self-retaining catheter was inserted to aid in maintaining cleanliness at the operative site.

There was no postoperative sepsis, and the circulation was very good. The pedicles were severed separately and

the newly formed sac rapidly assumed the appearance of a normal scrotum (Fig 8).

Some type of scrotal support must be worn for at least three months following this type of plastic operation in order to prevent excessive sagging.

Many of these cases heal without a plastic operation, but there are a certain number of cases,

FIGURE 8 Final Result

such as the one reported, in which, unless a plastic operation is performed, the testes and scrotum become so bound down by scar tissue that the urethra is involved, thus causing a stricture that later on in life may require operative interference.

SUMMARY

A case of extensive gangrene of the scrotum is reported, the treatment by the excision of necrotic areas and the use of zinc peroxide in cleaning up the infection is discussed.

A simple plastic operation for reconstructing the scrotum is described, which should be used only in those cases of extensive gangrene that may lead to stricture formation.

URETHRITIS FOLLICULARIS*

ISADORE J. ZIMMERMAN M.D.†

MANCHESTER, NEW HAMPSHIRE

AVAILABLE published works, including text books, are rather vague in their description and evaluation of the nodular or polypoid protruberances frequently encountered at the proximal portion of the female urethra and bladder neck. These nodules are visualized with the foroblique telescope and the McCarthy cystourethroscope by withdrawing the instrument into the urethra with the irrigating fluid actively flowing. Some are club-shaped, with a small pedicle, others are blunt, with a broad base. While they appear to be more commonly situated near the bladder neck, they may extend for a variable distance into the urethra. The nodules are covered by normal appearing mucosa. Careful observation usually reveals one or more blood vessels entering them at the base. These projections have been frequently referred to as inflammatory tags or polyps of the female urethra. Because of their obviously benign character, they have seldom been subjected to biopsy.

I have removed a few of these nodules from 3 women for microscopic study. The patients were in their third, fourth and fifth decades respectively. All 3 showed infection of the uterine cervix and pus and bacilli in the urine obtained by catheterization. Two had cystoceles with incontinence. One had a proved papilloma of the bladder near the right ureteral orifice, and a right pyelonephritis presumably associated with the mild obstruction occasioned by the papilloma. No patient had at any time had hematuria, although it was present in several of the reported cases of follicular lesions elsewhere in the urinary tract. The biopsy specimen in each case revealed a solitary lymph follicle with densely packed lymphocytes at the periphery and a typical germinal center (Fig. 1).

This lesion is not confined to the female urethra. Figure 2 shows the typical lymph follicle from a presumed polyp removed from the prostatic urethra near the internal orifice of a sixty-two-year-old man with a profound bacillary infection secondary to an infected hyperplastic prostate.

In one of the sections taken from the female urethra, lymph follicles and glandular structures were found in the same polypoid mass (Fig. 3). In the gross this structure differed not at all from the others.

Since there is a paucity of literature on urethritis follicularis, it should prove profitable to review briefly some of the more recent reports on follicular lesions elsewhere in the urinary tract. Kretschmer¹ in 1913 reviewed the literature on pyelitis follicularis and found only 7 cases. Of these the bladder was involved in only 2 cases, 1 of these being Kretschmer's. Hundley and Carson² in 1929 added 3 more cases of pyelitis follicularis to the literature. Hinman and Cordonnier³ stud-

FIGURE 1 Solitary Lymph Follicle in a Polypoid Mass Removed from the Proximal Portion of the Urethra in a Woman.

ied 7 cases of cystitis follicularis and biopsied 5. Six patients were women and 1 a man. The ages ranged from eight to sixty nine, although most of the patients were over forty. Colon bacilli were present in the bladder urine at intervals in all the cases. Colon bacilli were also reported in Kretschmer's case and in that of Von Frisch. Busch⁴ in 1905, by making serial sections of the urethra of cadavers, discovered lymph follicles in the fossa navicularis in 6 adult men ranging in age from twenty five to sixty seven years. He found none in the fossa navicularis of 2 newborn infants.

Pelouze⁵ reported 75 cases of what he designated as lymphocystic urethral lesions at and distal to the margin of the vesical outlet and attributed them to active tuberculosis. He later modified his

†Urologist, Sacred Heart Hospital.

view when he was able to find no demonstrable tuberculosis in some of the cases. In such patients, however, he found a concomitant prostatitis which could not be cured so long as the lesions were present. The lymphocystic bodies of Pelouze have been classified by Hinman midway between cysts and polyps. Because cystic degeneration of lymph follicles elsewhere in the body rarely, if

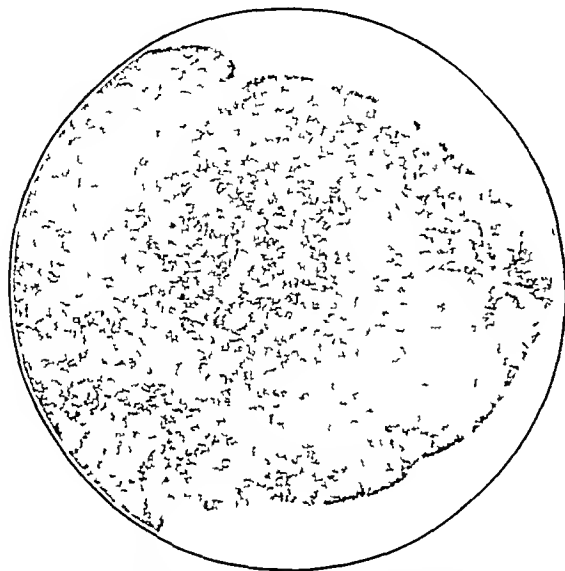

FIGURE 2 *Lymph Follicle in a Polypoid Mass Removed from the Prostatic Urethra in a Patient with a Profound Bacillary Infection*

ever, occurs, it does not seem proper to include them in the follicularis group.

Stirling⁶ recently added 4 cases of cystitis follicularis to the literature. One case was associated with cystitis cystica, cystitis glandularis and pyeloureteritis follicularis, and 1 exhibited cystitis follicularis and cystitis glandularis in the same specimen. In each case the urine was infected with colon bacilli.

True solitary lymph follicles have been found, then, in the renal pelvis, the ureter, the urinary bladder, the posterior urethra and the fossa navicularis.

Urethritis follicularis must be differentiated from the cystic, glandular and granular groups (with which it may, however, be associated), from true polyps, small fibromas or myomas which are probably not very common and from bullous edema. Because clinical differentiation may at times be difficult and because the lesion may have special significance in relation to associated pathologic lesions, exact diagnosis and therefore a rational therapeutic approach demand more frequent biopsies. Chronic infection, although not mentioned in every reported case presenting clinical

lymph follicles, appears to be an important factor.

Whether submucosal lymph follicles are normally present in the urinary tract has been a subject of considerable interest. Time does not permit a detailed discussion of this problem, which is ably presented by Busch, Kretschmer, Hinman and others. Lymph follicles have as yet not been reported in the urinary mucous membranes of infants. The manifestation of enlarged follicles in the presence of infection, however, would seem to point to the pre-existence of occult lymph tissue in the urinary mucous membranes, with perhaps in individual variation. Inasmuch as solitary lymph follicles occur in the mucous membranes of various other organs and because of the close embryological relation between the urinary tract and the alimentary tract, the absence of nodules appears

FIGURE 3 *Glandular Structures in a Polypoid Mass Removed from the Proximal Portion of the Urethra in a Woman*

The same specimen also showed two lymph follicles

more remarkable than does their presence. Their spontaneous disappearance from the bladder with the subsiding of infection has been reported. In this respect they do not differ greatly from the other proliferative lesions of the mucous membranes of the urinary tract. This phenomenon in each case suggests the necessary presence of a pre-clinical structure made manifest by the presence of infection. MacCallum,⁷ quoting Ribbert, points out that there are many scattered lymph follicles in the tissues which become evident only when they are caused to swell by some inflammatory reaction.

Not all patients with chronic genital or urinary

infection develop follicular manifestations. One or more additional coexisting factors must of necessity, therefore, be involved. Of these, a wide individual variation in the presence of submucosal lymphoid tissue in the urinary tract has been predicated as a most reasonable explanation. Recent experimental work with estrone in monkeys, while in no way refuting this theory, is of considerable interest.

Sandys and Zuckerman⁸ demonstrated small lymph nodules deep under the urethral epithelium in male rhesus monkeys, and showed that these nodules became manifest after the monkeys had been injected with estrone. The nodules increased in extent as long as the injections were given. Further studies on the relation of these follicles to hormonal influence and their possible relation to general and local defense mechanisms against infection and toxic products would be enlightening.

From available evidence I am led to look upon these follicles as secondary rather than primary manifestations of infection. Their presence therefore, whatever the associated symptomatology may be, should lead to a search for the primary cause, particularly in the urinary and the genital organs of both men and women. Being cognizant of the facts that lymphoid tissue is part of the body's defense mechanism against bacterial invasion and that the follicular nodules may be expected to disappear with the eradication of the primary source of infection, it would hardly seem logical to fulgurate them indiscriminately as polyps. If, however, by their location they interfere with the complete emptying of the bladder or are a source of irritation or disturbing hemorrhage, complete destruction with high frequency current would appear to be indicated.

SUMMARY

Microscopical study of polypoid masses removed from the posterior urethra of 3 women and 1 man showed the presence of true solitary lymph follicles in each case and associated glandular structures in 1.

Etiologically these nodules are apparently secondary to infection elsewhere in the genitourinary tract, although certain coexisting anatomical or physiological factors probably play an associated role.

A careful study of the genital and urinary tracts in both men and women, therefore, should precede any decision with regard to the relation of these follicular lesions to urinary signs and symptoms. This point of view should lead to a rational therapeutic approach.

DISCUSSION

DR. E. GRANVILLE CRABTREE, Boston. I should like to ask Dr. Zimmerman if these cases are sufficiently differentiated for them to be distinguished from round-cell infiltration.

DR. ZIMMERMAN (closing). The differential point between true lymph follicles and round-cell infiltration is the germinal center. In each of the two sections shown there was a light central portion and a darker peripheral area. The lighter central area is the germinal center which is not present in round-cell infiltration.

REPORT ON MEDICAL PROGRESS

SYPHILIS

C GUY LANE, M.D.,* AND G MARSHALL CRAWFORD, M.D.†

BOSTON

SYPHILIS has been widely discussed in the past year as a result of the campaign of the United States Public Health Service, both in the medical and in the lay press, for its eradication. While only a few of these articles can be commented on, this publicity has resulted in wider discussion of the disease by the general public and greater familiarity with its manifestations and treatment. Numerous laws relating to syphilis have been enacted, some of them prematurely without due consideration of all phases of the question.

SYPHILIS AND PUBLIC HEALTH

At least forty-four states have either laws in effect or bills before their legislatures to create new laws or revise existing statutes. In Massachusetts a prenatal blood-test law became effective on November 1, 1939, and requires every physician to perform a serological test in every pregnancy.¹ The incidence of syphilis in pregnant women in various parts of the country in large clinics has been found to be from 2 to 4 per cent.² The fact that the loss from syphilitic blindness in the United States has been estimated at ten million dollars yearly³ is a potent argument for such laws.

Much has been written about these laws. Kolmer's⁴ article on premarital and prenatal tests for syphilis is a particularly good summary of the reasons for and against such tests for syphilis, and sums up with clarity the problem of the legal requirement of blood tests for syphilis during pregnancy and at delivery. The principle involved in the formulation of statutes for the control of syphilis has been thoroughly considered by Stokes and Ingraham,⁵ who have also discussed the matter of false positive serological tests occurring in syphilis. They emphasize that laws cannot justly put the sole or major dependence on any laboratory procedure. The proper interpretation of serological tests for syphilis is vital. A single negative report does not of itself rule out the disease, and a repeated checking of positive re-

ports in the absence of other confirmation is essential. A series of papers by Stokes,⁶ Snow,⁷ Nelson⁸ and Towne⁹ is a most comprehensive symposium on the social and public-health programs. Many phases of control, diagnosis and legal regulation are thoroughly discussed, while educational and co-operative measures are emphasized. The follow-up of the syphilitic patient is an essential feature of any program, because every early case may be a clue to a new localized outbreak, and sometimes a surprising number of infected individuals can be unearthed by adequate follow-up methods. This group of papers is most worthy of careful study by those interested in the problem.

It is worth mentioning that the fifth and sixth supplements¹⁰ of *Venereal Disease Information* are a useful help to the general practitioner in the handling of syphilis. These concise booklets should be regarded merely as a guide and not as a thorough dissertation on the subject matter.

In any attempt to develop statutory control of syphilis there are three essential features: first, an adequate educational campaign over a period of years to obtain the co-operation of physicians and the public; second, a preservation of the opportunity for individual medical interpretation by properly qualified physicians of the complex problems which arise; and third, the insistence on an adequate physical examination as well as on laboratory procedures.

EXPERIMENTAL RESEARCH

Perhaps the one outstanding advance of the year is the work of Eagle¹¹ on the in vitro effect of arsenic and bismuth compounds on *Treponema pallidum*. Years ago unsuccessful attempts had been made along this line. Eagle's success opens many vistas of perhaps startling advances. Time consuming animal experiments on the therapeutic activity of various drugs may possibly be replaced. More accurate information on the mode of action of drugs may be obtained. This work of Eagle has already been applied from the clinical standpoint by the successful use of arsphenaminized citrated blood in the prevention of transfusion syphilis.¹²

Turner and his associates¹³ report that some

*Clinical professor of dermatology and syphilology, Harvard Medical School; chief, Department of Dermatology, Massachusetts General Hospital.

†Assistant in dermatology and syphilology, Harvard Medical School; assistant in dermatology, Massachusetts General Hospital.

degree of protection is afforded by syphilitic human serum in experimental rabbit syphilis. This substantiates the occurrence of protective antibodies in the serum of human syphilitic patients. Becker¹⁴ has done similar work, utilizing a flocculate obtained from syphilitic human serum, and has shown that this material is antigenic. Landsteiner's haptene theory offers the best explanation of the mechanism involved, in Becker's opinion.

The massive therapy method has been pursued still further. This method of treatment, while holding a great deal of hope and promise, cannot be accepted until ten or fifteen years' observation bears out the results of a so far maximal period of five years' observation. Several European investigators using the technic have reported a high incidence of reactions. In this country the work of Chargin and Hyman¹⁵ and their collaborators seems to have been most carefully carried out and their results are more satisfactory than others reported, but complications are undesirably high in number. It should be emphasized that this type of therapy is still in an experimental stage. It is unsuitable for mass application and probably always will be.

DIAGNOSIS

An advance in the laboratory diagnosis of syphilis has been made in the development by Krajian¹⁶ of a staining method for *Treponema pallidum* in tissue sections. This stain for smears containing the organism had been previously reported and has had a wide clinical application. The frozen-section method has some advantages over the dark field and smear-stain methods, but it involves a delicate technic.

SEROLOGY

There has been further search for a more rapid serological technic. Many reports¹⁷ have appeared concerning the use of the Laugblen test for syphilis, which is comparatively new and rapid, but there is considerable disagreement in the reports. This method deserves further study.

Standard procedures should be employed until there has been wide experience with new methods. Comparative studies of the merits of already established serological procedures continue to be reported. The value of routine employment of a very sensitive flocculation or precipitation test, checked by a less sensitive but sometimes more specific complement fixation method, has been emphasized by Tuft and Richter¹⁸ in reviewing the Kline, Kahn and Kolmer methods.

Clinical confirmation of various serological procedures has been subjected to further study. Crawford and Ray¹⁹ have reviewed a large series of

serological discrepancies, and point out that a persistently positive Hinton test, even though unaccompanied by a positive Wassermann reaction, may be considered diagnostic of syphilis. When exhaustively studied 50 per cent of the cases in this large group were found to exhibit other evidence of syphilis. Serological discrepancies are continually arising and need further extensive study. It is important that in questionable cases there be repeated retesting of blood by several methods in different laboratories and searching physical examination. The question of false positives arises, but the temporary occurrence of a reagin-like substance has rarely been found in the blood of some otherwise normal individuals.²⁰ Various bacterial diseases other than syphilis and certain noninfectious diseases may give rise to this situation.²¹ Infectious mononucleosis has been found to give an occasional false positive.²² Further evidence has appeared which verifies previous assertions that malarial infections may cause a temporarily positive Wassermann or Kahn reaction.²³ It is possible that a solution of these enigmas lies in a more extensive application of quantitative serological methods. Kahn²⁴ cites many advantages of such a procedure. It is to be emphasized that an ordinary qualitative test reported as "++++" means nothing except that it is positive, giving no quantitative information.

Whether a negative Hinton test rules out neurosyphilis in the absence of clinical evidence and thus obviates the necessity of spinal puncture is still a controversial point according to Hazen,²⁵ who states that from 15 to 20 per cent of cases of neurosyphilis will be found to have a negative blood serological test even with the most delicate methods. The Davies-Hinton reaction performed on spinal fluid is reported by Marquis²⁶ and Brenner and Merritt²⁷ to have a higher degree of specificity and sensitivity than has the Wassermann test. Further study is indicated, and meanwhile both tests should be continued on spinal fluid specimens.

CLINICAL PROBLEMS

Late asymptomatic syphilis has been emphasized by a number of studies during the past year. The prognosis of the so-called latent group was reviewed by Morgan²⁸ who found that life expectancy is shortened approximately 17 per cent in these patients. The amount of activity found to occur subsequent to the diagnosis of latent syphilis was said by this author to be 25 to 35 per cent. Adequate treatment of this group of syphilitic patients reduces the morbidity to 5 per cent. Even if the figures quoted by Morgan are a little higher than might be expected by some

authorities, they should serve as a warning to those who would summarily dismiss asymptomatic late syphilis. O'Leary²⁹ in a review of latent syphilis emphasizes the fact that adequate treatment in the early stages would prevent the appearance of incapacitating or death-dealing complications in 98 per cent of patients. The present incidence of 60 per cent asymptomatic syphilis would thus be theoretically reduced to 2 per cent. The point should be brought out here that the continuation of O'Leary's "permanent latency" will not be maintained by the patient's self-generated resistance in some cases. A short course of bismuth once or twice yearly will obviate trouble in practically all cases.

Beckh and Kulchar³⁰ state that too long usage of any one drug may be partially to blame for resistance to treatment. They also found that the simultaneous use of two drugs seems to contribute to treatment resistance, perhaps owing to underdosage with the arsphenamines.

SYPHILIS AND TUBERCULOSIS

A number of articles have appeared in regard to coexistent syphilis and pulmonary tuberculosis. An analysis of the more recent reports seems to indicate that the two diseases can occur in the same patient without undue exaggeration of either, except in the Negro. Patients with pulmonary tuberculosis appear to tolerate anti-syphilitic therapy as well as nontuberculous individuals. The effect of tuberculosis on the serological reactions for syphilis has been a rather controversial point for some years. Parran and Emerson³¹ state that tuberculous toxemia may contribute a confusing factor to the serological study of syphilis, but should not present a major problem in the clinical interpretation of results obtained with carefully conducted serodiagnostic procedures.

CARDIOVASCULAR SYPHILIS

Recent studies indicate a gradual diminution in cardiovascular syphilis. Welty³² reports the clinical and pathological records of 15 000 consecutive postmortems over a ten-year period. His figures bear out the impression of both the decrease in incidence of cardiovascular syphilis and its lessening importance as a cause of death. A study by Thompson, Comeau and White³³ of syphilis of fifteen to twenty-five years' duration revealed only 7 per cent of cases as having definitely demonstrable cardiovascular syphilis. None of the cases having had even a minimum of adequate therapy were among the 7 per cent with cardiac damage. This supports the value of therapy in the prevention of cardiac syphilis.

NEUROSYPHILIS

A concise review of the treatment of neurosyphilis by Merritt³⁴ is a partial guide for the general practitioner. Kopp and Solomon³⁵ studied the malarial treatment of 302 cases of general paresis. The best clinical results were obtained in those patients who received one hundred and fifty hours or more of temperature exceeding 100°F rather than extremely high temperatures. Patients receiving more than ten paroxysms obtained better clinical results than did those with less.

Observations indicate that the prognosis in paralytica dementia is strongly influenced by the personality pattern. The schizophrenic type should be viewed as of very grave prognostic significance.³⁶ Patients in the delirious, apathetic and agitated groups have the best prognosis, especially those with a well-integrated preparalytic personality.³⁷

Thiamin chloride has been found useful for certain cases of lightning pains in tabes dorsalis. Metildi³⁸ treated a small series of cases with parenteral injections of this drug at weekly intervals. It has been our experience, however, and that of O'Leary³⁹ that very large daily intravenous doses are usually necessary to produce results.

SYPHILIS IN PREGNANCY

A rather harsh criticism of the routine therapy generally accepted for pregnant syphilitic women has been made by Ingraham,⁴⁰ who questions so much active arsenical therapy during pregnancy. Naturally any physician will give full consideration to the physical condition of the individual woman patient in planning treatment for the remainder of the pregnancy, and will weigh carefully the risks of treatment and the possibility of a syphilitic child. Moore⁴¹ in commenting on this paper points out that bismuth alone has not succeeded in preventing congenital syphilis, and that the abandonment of arsenical therapy during pregnancy would most certainly increase the incidence of congenital syphilis.

CONGENITAL SYPHILIS

A most excellent treatise on the diagnosis of congenital syphilis by Black⁴² is well worth reading in toto. Clear tables illustrate the essential pathognomonic criteria. The vital necessity of diagnosing congenital syphilis at the earliest possible time in life and the institution of effective treatment as soon as the diagnosis is established are emphasized. No treatment should be given without an absolute diagnosis, and if the child of a syphilitic mother gives negative reactions the follow-up should continue over a period of years.

in all cases. Offspring of syphilitic women may exhibit no diagnostic evidence of any sort until the age of five years or later. This author also strongly advises lumbar punctures in all congenital syphilitic patients. Hinsie⁴³ reports on neurosyphilis in children, and quotes the striking incidence of 33 per cent positive spinal-fluid findings when routine lumbar punctures were done on congenital syphilitic patients with positive serological blood tests.

The ocular manifestations of congenital syphilis are reviewed by Kahn⁴⁴ and McLeod⁴⁵. The former states that the eye is more frequently affected than is any other organ in congenital syphilis and that there is a higher percentage of ocular lesions than of positive blood serological findings. A report by Klauder and Cowen⁴⁶ on corneal examination by slit lamp microscopy in the diagnosis of late congenital syphilis is of considerable interest. Its use is essentially restricted to ophthalmologists.

Several reports on the treatment of congenital syphilis bear out the importance of full therapeutic doses in accordance with weight rather than age, and the usefulness of therapy even in older congenital syphilitic patients. Acetarsone is not finding as much favor as formerly, later reports indicate less satisfactory results and higher morbidity, due to complications and reactions, than was originally hoped.

THERAPY

Although new preparations of arsenic continue to be studied, it seems that bismuth is at present in the foreground of the investigative field. Reports on toxicity, absorption, excretion, retention and therapeutic activity coincide with previously accepted knowledge of the various bismuth compounds. A simplified technic for administering old arsphenamine is reported by Cannon⁴⁷. It is useful for those employing this drug in office practice. A similar technic has been used for many years at the Massachusetts General Hospital.

Acetarsone has been studied further by Pillsbury and Perlman⁴⁸. The effect of this drug in arresting congenital syphilis is inferior to arsphenamine and bismuth preparations, and the incidence of reactions is high. This drug cannot be experimentally controlled in regard to toxicity or effectiveness as can the other arsenicals. One cannot be sure that patients are taking their medication as directed. This objection applies to any oral treatment of syphilis. Robinson and Robinson⁴⁹ report that Acetarsone is a dangerous drug. They state that it is definitely contraindicated for adults and also issue a warning about self medication.

Several papers have appeared in regard to the simultaneous use of arsenic and bismuth compounds. The bulk of opinion seems to be against this combined treatment. Disadvantages include higher risk of damage to the patient, slower reversal of serological tests⁵⁰ and a higher incidence of relapse. Beckb and Barnett⁵¹ support this attitude. They report almost four times as high a percentage of mucocutaneous relapses among cases treated with arsenic and bismuth simultaneously. The alternating continuous system therefore seems to be preferable.

Mention was made in last year's report of oral bismuth therapy in syphilis. Work along that line has been continued, and very recently further reports of the clinical application have appeared. It is believed that considerable caution should be exercised in the application of any oral treatment for syphilis. It will always be difficult, even with the most co-operative patient, to be certain that the prescribed dose of oral medication has been received. The patient will tend to stray farther from the influence of the physician, thus reducing the probability of co-operation. In the place where such therapy would be of the greatest economic value, namely the indigent population, oral medication would be without doubt the most abused. The results would be an inevitable increase in relapse and spread of the disease. We cannot know for many years the ultimate effect of any new type of medication for syphilis. A most serious danger to the public health is the possibility of self-treatment which oral therapy for syphilis is bound to encourage. Oral medication should be restricted to certain very narrow limitations, which might include patients unable to secure regular treatment by a physician, the occasional unusual patient who cannot tolerate intramuscular injections, perhaps some cases of cardiovascular syphilis and a few selected cases of congenital syphilis. A recent editorial⁵² gives a concise summary of this situation.

TREATMENT REACTIONS

Erythema of the ninth day has received considerable attention. It is now relatively well accepted^{53, 54} that this reaction is not a contraindication to the continuance of intravenous arsenicals, but a temporary reduction in the dosage is advocated. Complications of the ninth-day erythema, such as jaundice, prolonged dermatitis or hematologic disturbances, are a definite contraindication to arsenicals, at least for a considerable time after recovery. It is essential to differentiate this eruption from the early stages of exfoliative dermatitis. One case has been reported in association with bismuth therapy⁵⁵. It has also occurred following gold injections.

Gastric intolerance to the arsphenamines is discussed by Irgang⁵⁶ in a lengthy but interesting treatise. One warning seems essentially worth while. He states that any arsenical hepatitis not responding to three weeks of routine detoxication therapy should be watched with exceptional care, as this may presage yellow atrophy of the liver.

Post-arsphenamine jaundice was studied by Lane⁵⁷ in a review of 100 cases. The four factors of causal importance in this series were arsenic, syphilis, bacterial infections and bismuth. Bismuth appeared to be a precipitating factor to a larger degree than is usually expected. Soffer⁵⁸ reviewed all the reports of jaundice in the available literature. He found that 1 per cent of syphilitic patients develop jaundice. From 1 to 14 per cent of those having jaundice were reported to have developed yellow atrophy of the liver. This is a disturbing percentage. Cirrhosis of the liver may play a greater part than is generally realized. The use of cholagogues and cholaretics is held to be an unsound form of therapy.

Tryparsamide reactions have lately been reported. These include numerous nitritoid reactions, occasional dermatitis and a case of acute yellow atrophy of the liver. This drug until relatively recently was not known to cause any reaction other than damage to the optic nerve. A detailed and comprehensive review of the literature on tryparsamide was recently published by Hinrichsen.⁵⁹ It is assumed that there may have been an unnoticed deviation in the method of manufacture or possibly an unintended alteration in the basic materials used. These matters are being investigated.

Optic nerve damage from tryparsamide is being investigated by Muncy,⁶⁰ and he reports that the vitamin B complex seems to act as a preventive. This author has also used the vitamin B complex as a curative agent after tryparsamide damage has begun to appear; large doses should be used in these cases. Muncy believes that preparatory bolstering of the patient with the vitamin B complex before the use of tryparsamide is of considerable value.

Astrachan⁶¹ indicates that the administration of liver extract seems to help in preventing reactions of intolerance to arsenicals. It may be of some help in hastening recovery from the aftereffects of arsenic intolerance.

* * *

That definite progress is being made in the control of syphilis is indicated in a recent release of the United States Public Health Service.⁶² Not only have the facilities for diagnosis and treatment been greatly enlarged, but 60 per cent more persons have been brought under treatment than in the previous twelve months. Approximately

103,000 patients were discharged from clinics as cured or arrested, as compared with 78,000 in 1938. Such figures lend encouragement to the campaign against syphilis.

CASE RECORDS OF THE MASSACHUSETTS GENERAL HOSPITAL

ANTEMORTEM AND POSTMORTEM RECORDS AS USED
IN WEEKLY CLINICOPATHOLOGICAL EXERCISES

FOUNDED BY RICHARD C. CABOT

TRACY B. MALLORY, M.D., *Editor*

CASE 26061

PRESENTATION OF CASE

A sixty-year-old Italian barber was admitted complaining of severe epigastric pain.

Twenty years before he had been examined at an outside hospital for the question of peptic ulcer, but the diagnosis had not been established. He was well from then until six months before entry, when he began to complain of indigestion characterized by a sense of epigastric fullness. Two weeks before entry this symptom had become worse and for the first time he began to notice vague epigastric pains. Fourteen hours before being seen he had a sudden onset of severe, prostrating, epigastric pain. He vomited a small amount of material described as resembling coffee-grounds. His local physician was called and gave him some medicine in water to drink. This produced great accentuation of the abdominal pain. The doctor was called back again four hours later, at which time the patient was found in collapse. There was definite cyanosis, dyspnea and a weak thready pulse, and the blood pressure could not be obtained. The abdomen was somewhat distended, and was tender, particularly in the upper half, there was moderate spasm. The patient was referred to the hospital after he had been given two $\frac{1}{4}$ -gr doses of morphine.

Physical examination showed a well-developed and nourished man, who was cyanotic, with gasping respirations and a weak and thready radial pulse, markedly dehydrated and too ill to respond to questions. The heart sounds appeared normal, at about the rate of 110 beats a minute. The chest was clear to auscultation except for a few moist rales. The abdomen was moderately distended throughout. There was diffuse tenderness, most evident in the epigastrium and under the left costal margin. There was definite spasm of the entire epigastrium. Auscultation revealed no audible peristalsis. The flanks bulged somewhat, giving one the impression of fluid in the peritoneal cavity, the liver dullness was not obliterated. Rectal examination was negative. There was slight pitting edema of both ankles. The blood pressure was 60 systolic, 40 diastolic.

The temperature was 101°F .

The blood showed a red-cell count of 4,100,000

with 110 per cent hemoglobin, a white-cell count of 7400, and a normal differential.

X-ray examination in sitting posture revealed no air under the diaphragm and gave evidence of intestinal ileus because of one slightly dilated loop of small bowel containing a fluid level. The roentgenologist suggested that the radiance of the film was evidence of free fluid in the abdomen. There was also evidence of some fluid in the left pleural cavity. The patient's condition contraindicated exploration, particularly as no diagnosis could be arrived at. He was given a transfusion and Ochsnerized. Four hours later, examination showed the patient's condition to be somewhat worse. The abdomen was more distended and more spastic. The chest signs had changed remarkably, there being complete immobility of the left chest, with flatness to percussion and no breath sounds. Bronchial breathing, with increased fremitus, was heard at the right base. A chest tap through the left eighth interspace yielded a large amount of dirty brown fluid, which was odorless and was shown on smear to contain red blood cells in various stages of degeneration and amorphous yellow material presumed to be hemoglobin, a rare gram-positive diplococcus was seen. Six hours later the patient died.

DIFFERENTIAL DIAGNOSIS

DR. TRACY B. MALLORY. Once in a long interval it seems only fair to turn the tables and today they have given me a case to discuss from the clinical point of view. After reading the history I wondered why this case was chosen for me and tried to decide whether it was to be regarded as a manifestation of touching faith on the part of my colleagues or of a vindictiveness that I hate to contemplate.

We are faced here with the paradox of a man with a perfectly clear story of an abdominal catastrophe whose only unequivocal clinical findings seem to be in the thorax. If we take the story alone we have a man, who previously had been in good health except for the vaguest of prodromal symptoms, suddenly developing prostrating abdominal pain, who in a period of a few hours goes into shock. That immediately makes one think of a perforated viscus, possibly of acute hemorrhagic pancreatitis or of mesenteric thrombosis,—although the pain is repeatedly described as epigastric rather than abdominal,—and conceivably of aneurysm, although there is no mention of pain in the back. With the old history of a question of ulcer twenty years ago, with the vomiting of some material described as coffee-grounds,—we wish we could rely on that and that we had some objective evidence to confirm it,—one would

think first in terms of peptic ulcer, and strongly suspect perforation. We look for evidence of the development of general peritonitis and get suggestive evidence of it, but the signs and symptoms all remain localized in the upper part of the abdomen and in the epigastrium. Now sometimes clinical signs of peritonitis such as this indicate a peritonitis limited to the lesser omental cavity, and an ulcer might easily perforate into that, and he might not yet have a general peritonitis.

The question comes up whether this is true shock or possibly response to hemorrhage. It sounds to me rather more like a picture of shock. The cyanosis fits that better. The constantly maintained low blood pressure sounds like shock, as does the fact that several hours later he still had a hemoglobin of 110. His blood was apparently concentrating rather than showing evidence of anemia, which makes shock more likely than hemorrhage.

I cannot, however, think of any ordinary complication of gastric ulcer that could produce what we find later. We have the statement that when he was first seen the thorax was negative to auscultation. I think we probably have to take that with a grain of salt. The examiner was probably thinking of an abdominal condition, as I thought when I read to that point, and I do not rely on that observation. Moreover, at the time he came to the x-ray department they had already found that there was something in the thorax. On the next clinical examination the breath sounds were diminished. Soon they disappeared completely over the left chest, which became fixed, no longer showed respiratory movements and was flat to percussion. Eventually they tapped it and got off material that we are led to believe was indicative of old hemorrhage.

So we have to consider the possible thoracic lesions, and there are several, which produce the picture of shock and pain localized in the abdomen. Coronary thrombosis can certainly do it, but coronary thrombosis could not account for the fluid which was withdrawn on chest tap unless there was also a rupture of the heart and the pericardium was so distended that they succeeded in tapping it. This material which was withdrawn, if we are right in our assumption that it is blood showing evidence of disintegrative changes, must have been acted on by ferments in order to change its consistence and color. Blood in a serous cavity does not undergo this change for days, so that the assumption of a ruptured heart would force us to assume that the disease is of much longer duration than the history would indicate. That does not seem a satisfactory explanation. Infarcts of the heart do not perforate for a number of days,—four, in my experience, is about

the minimal time for them to occur,—and we have nothing to suggest that anything so severe as infarction of the heart occurred four days before the present illness. So I am inclined to rule out infarct of the heart and hemopericardium. Pulmonary embolus can produce shock. The story does not sound very much like it, but it can produce abdominal pain and it can produce pleural effusion which can be bloody, but again the time is too short for this to have become old, changed blood.

This seems to eliminate most of our possibilities except for the organs which pass from the thoracic into the abdominal cavity, and one certainly must think of the aorta. It is quite possible, I think, for a rupture of the aorta in the very low thoracic or upper abdominal region, bleeding perhaps into the leaves of the diaphragm, to result in blood in both the abdominal and pleural cavities simultaneously or one shortly after the other. We are without benefit of the results of serological tests, and sixty is a little late for a luetic aneurysm. So if it is rupture of the aorta, it is probably one due to senile ectasia or a deep atheromatous ulcer rather than to a syphilitic aneurysm.

There is one other possibility which certainly comes to mind. Every now and then the stomach is not in the abdominal cavity but in the thoracic cavity. That would explain most of the symptoms here. I think we should still have to assume a rupture of the stomach, the extravasation of material into the hernial sac would completely fill the pleural cavity and would also probably extend down into the lesser omental sac and account for the suggestive signs of peritonitis that we have there. Though that seems like a fanciful hypothesis, it would be my first guess. If there are some x-ray plates I should like to have Dr. Hampton show them before I finally commit my self.

Is that a fluid level on the left side?

DR. AUBREY O. HAMPTON: Yes.

DR. MALLORY: How high?

DR. HAMPTON: At the eleventh interspace posteriorly. It is more the shape of the fundus of the stomach than it is that of the small bowel.

DR. MALLORY: Can you tell where the level of the diaphragm is?

DR. HAMPTON: No. At the time of the x-ray examination he had extensive density in the left side of the chest which might have influenced the physical examination somewhat later on. He was turned on the left side, and the film was taken to show free air but none was seen. I do not believe the radiologist was justified in calling this a loop of the small bowel, its interpretation is

the most important thing. The fundus of the stomach is probably below the diaphragm.

DR MALLORY: I should probably listen to Dr Hampton but the quality of the plates is certainly very poor, and I will stick to my two previous diagnoses. I will put diaphragmatic hernia with rupture of a thoracic stomach first, and aneurysm as the second possibility.

DR HENRY NIGRO: I took care of this man, and I might say that when the aspiration was done the fluid did not look like anything that is often seen. It was neither pus nor clear fluid. They did examine a stained smear, and a couple of gram-positive diplococci were found. Dr Chapman saw him a few hours later, and after looking at this material, which had a dirty brown appearance, he thought of testing it with Töpfer's reagent. When that was complete it was evident that the fluid was gastric contents.

DR MALLORY: I meant to say that I wished this material, described as odorless, had been sniffed by Dr Richardson or someone in whose nasal sensorium I have complete confidence.

DR GRANTLEY W TAYLOR: Why would not carcinoma of the upper part of the stomach with perforation both ways account for the findings?

DR MALLORY: I think that is a good idea and should have been suggested.

DR ALLEN G BRAILEY: I should think perforation of a peptic ulcer through the diaphragm might be possible.

DR FRANCIS T HUNTER: I should like to emphasize the fact that I do not know of any way of turning hemoglobin into "amorphous yellow material." That description is misleading.

CLINICAL DIAGNOSIS

Rupture of peptic ulcer of esophagus

DR MALLORY'S DIAGNOSIS

Rupture of intrathoracic stomach

ANATOMICAL DIAGNOSIS

Rupture of peptic ulcer of esophagus

PATHOLOGICAL DISCUSSION

DR BENJAMIN CASTLEMAN: Here is the specimen that was removed at autopsy (Fig 1). There was no diaphragmatic hernia, but what had occurred was a perforation of a peptic ulcer of the lower end of the esophagus. It had perforated into the left pleural cavity, had dissected posteriorly and retroperitoneally down to the abdomen for a short distance and terminally into the peritoneal cavity. There were 2000 cc. of fluid in the left pleural cavity. Unfortunately, we have

not yet been able to get microscopic sections of the ulcer but it is most likely a peptic ulcer arising in ectopic gastric mucosa in the esophagus. This is the usual cause of these ulcers, although simple autodigestion is sometimes given as the explanation. Since peptic ulceration has a characteristic fibrinoid base it should be quite easy to recognize.

FIGURE 1 *Perforated Peptic Ulcer of Esophagus*

DR. EDWARD HAMLIN, JR: I should like to emphasize the sequence of events. The chest was essentially negative when the patient was first seen. Apparently what happened was that the mediastinal mass dissected retroperitoneally first, thus causing abdominal symptoms, and a few hours later ruptured into the left chest. The sequence of events was quite startling to say the least. So far as I can tell from the clinical and the pathological records there has been only one other esophageal perforation. That was the case of Dr Richardson's that was discussed at one of these conferences several years ago. It is apparently a relatively uncommon catastrophe. More often the ulcer penetrates into the aorta and the patient dies of hemorrhage.

DR. EARLE M. CHAPMAN I saw this patient, and while discussing the case with the house officer, after having been told all the clinical picture, he said "If this is an ulcer on the lower end of the esophagus that perforated, this fluid might be gastric contents." I thought it was an excellent idea, and so we did a gastric analysis and found combined acid present. We then made the diagnosis. Unfortunately, Dr. Mallory did not have that information beforehand.

CASE 26062

PRESENTATION OF CASE

A thirty-three year-old Italian laborer was admitted complaining of pain in the epigastrium.

Five years before admission the patient noticed a lump in the right pectoral region which gradually grew larger and finally painful. Two years before entry the mass was removed in an outside hospital. The pathological report, checked at this hospital, was "lymphosarcoma, lymphocytic type." Because pain persisted in the operative site the patient was referred to the Tumor Clinic where, during an eighteen month interval, he was given roentgen therapy over the region of the axilla. The pain was relieved, and a few smaller palpable nodes in the area disappeared. He received only 1200 r in all. Throughout this interval he remained in excellent general health and was able to continue work. During frequent follow up visits his chest remained clear and his physical examination negative, except for the finding of a small nodule in each axilla when last seen three months before admission. One month before entry, however, he felt a mass in the epigastrium after urination. Fourteen days before admission his house caught afire, he narrowly escaped death as he leaped down a flight of stairs to avoid the conflagration. He was excessively worried because of the loss of all his possessions, and two days later grew aware of a burning epigastric pain occurring daily before breakfast, relieved by drinking coffee and recurring a few hours after the evening meal when it was alleviated by "soda water." Throughout this latter illness he experienced no vomiting, weight loss, anorexia or black or tarry stools. Except for the fact that his brother had "ulcers," the patient's family, marital and past histories were negative.

Physical examination revealed a well-developed and nourished man who lay flat and quietly in bed. He was pale and complained of pain in the epigastrium and rectum. There were pea-sized shotty enlargements of the left axillary, the epitrochlear and the inguinal lymph nodes. The

heart and lungs were normal. The entire epigastrium was tender, but exquisitely so in the mid epigastrium. On inspiration a hard, round-edged spleen was felt to descend two to three finger breadths below the costal margin. There was a painful, tender rectal sphincter, but no fissure or other abnormality was observed to explain this finding. The blood pressure was 125 systolic, 60 diastolic.

The temperature was 100.6°F., the pulse 100, and the respirations 24.

Examination of the blood showed a red-cell count of 4,200,000 with 72 per cent hemoglobin, and a white-cell count of 4200 with 74 per cent polymorphonuclears, the smear was essentially negative. A stool specimen showed a + guaiac test. Gastric analyses, both before and after histamine, revealed no free acid and a total acid of only 5 units.

A gastrointestinal x ray series showed that the stomach was displaced to the right by a markedly enlarged spleen. The folds of the stomach, particularly those of the body close to the lesser curvature, were thickened. The remainder of the organ was negative. The duodenal cap showed no evidence of disease. There was no evidence of ulcer. Films of the chest showed a high diaphragm particularly on the left, apparently due to an enlarged spleen. There was no evidence of intrapulmonary disease.

The patient ran an elevated temperature, which ranged between 100 and 103°F., throughout his seven-day hospital stay. Four days after admission he suddenly developed a sharp, stabbing pain with exquisite tenderness in the left upper quadrant. The constant, mid-epigastric distress and tenderness remained unchanged, however. The white-cell count rose from 4000 to 7000. At 9:00 p.m., on the seventh hospital day, he was seized with another severe, now mid-epigastric, red hot poker like pain, distinct from that which remained in the left upper quadrant. He vomited a mouthful of fresh bright red blood and continued to retch, with much nausea, until he had brought up 400 cc. The patient was given morphine sulfate ($\frac{1}{4}$ gr., repeated fifteen minutes later) and a few swallows of sodium bicarbonate solution, both of which brought relief from vomiting and a diminution in pain. He sweated profusely, and the pulse became thin and irregular, at 150 beats per minute. One hour after the episode had started, his respirations became rapid, irregular, deep and gasping. This change became increasingly more pronounced, and a half hour later, or one and a half hours after the onset, respirations ceased.

DIFFERENTIAL DIAGNOSIS

DR. TRACY B. MALLORY I might say that the x-ray treatment was given here at this hospital. The original biopsy was done outside, but we saw the slides.

DR. ROBERT R. LINTON So you confirmed this diagnosis?

DR. MALLORY We apparently did.

DR. LINTON May I see the x-ray films?

DR. GEORGE W. HOLMES Normally the diaphragm is a little lower on the left than on the right. Here it is higher, and the space between the fundus of the stomach and the diaphragm is increased, all of which confirms the statement in the text that he had a mass in the left upper quadrant, probably an enlarged spleen. In the stomach there is a peculiar appearance of the mucosal pattern, extending from the cardiac orifice down along the lesser curvature. I should think that was definitely abnormal. One would like to have had further observations. Evidently the man who did the examination thought the appearance was abnormal and described it as a prominent fold. From these films I cannot say anything very definite about the pyloric end of the stomach. The sphincter looks all right, the cap looks all right. What could it be? Lymphoma could produce prominent mucosal folds and nothing else. That is a possibility. Gastritis could do it—local gastritis. I think varices in the stomach could do it. We have never seen, or at least I have never seen, varices in the stomach, we have looked for them, and we have had some cases that at autopsy were proved to have had them as a cause of hemorrhage. But if one did see them I should think they would look something like this.

DR. LINTON Was the esophagus examined for varices?

DR. HOLMES They do not state whether it was or not, but it is a routine procedure in our clinic.

DR. LINTON We have a man of thirty-three years of age who was admitted to the hospital because of pain in the epigastrium. Seven days after he was admitted he suddenly died, and it is up to me to explain the cause of his death. I believe that his exitus was due to hemorrhage, and I have to discover the origin of this hemorrhage. In reading over the history and physical examination, he presents two outstanding findings—hematemesis and splenomegaly. I am a little uncertain how much emphasis to place on the diagnosis of lymphosarcoma because the mass was a little unusual in location, especially without any other enlargement of the lymph nodes. By x-ray there is no enlargement of the mediastinal

glands, and I rather think that the treatment with 1200 r was a small dose. Is that right, Dr. Holmes?

DR. HOLMES Not if the diagnosis was correct.

DR. LINTON The mass that he noted in the epigastrium after urination I should gather was most likely the spleen that was felt on physical examination. The laboratory studies are not helpful. I should like to know whether a Hinton test was done. Since it was not included here, it probably is of no significance, but it is one of the possibilities that has to be considered. The gastric analysis is of interest in that he had no free hydrochloric acid even after histamine.

In reviewing the case we must consider the causes of hematemesis. I think that one can rule out any esophageal cause of hematemesis, such as varices, mediastinal growth or perhaps an aneurysm rupturing into the esophagus, because of the lack of evidence by x-ray and physical examination of disease in these structures. Passing on to the stomach and duodenum we have to consider ulcer and carcinoma, which I think are pretty well ruled out by the x-ray examination. There is also the possibility he had an abdominal aneurysm with rupture into the stomach, but there is no record that there was an expansile pulsation in the abdomen, so we can rule out that possibility. We do have an x-ray diagnosis of gastritis, and it is possible to have a severe degree of hematemesis from gastritis, so that I think that is a likely possibility—one which we should consider seriously. Another important cause of hematemesis is portal cirrhosis with splenomegaly, but I am not aware that one can get hematemesis from portal cirrhosis without esophageal varices. There are other rare conditions, such as the splenic vein thrombosis of Banti's disease, but again esophageal varices are necessary to explain hematemesis. There are certain other diseases, such as a primary blood dyscrasia, in which hematemesis is a possibility, but they are ruled out by the negative laboratory findings. I believe Hodgkin's disease and the various other forms of lymphoma are conditions which may cause hematemesis, though I am uncertain as to the mechanism. Syphilis is certainly to be considered in view of the fact that he had multiple, enlarged lymph nodes.

Did you find any record of the Hinton test, Dr. Means?

DR. J. H. MEANS This is very disturbing. The blood was taken, but the Pathology Laboratory did not report it!

DR. LINTON We have a young man with an enlarged spleen who had a sudden exitus from hemorrhage. I do not see how one can get away from the pathological report of lymphoma. It

is disturbing to me that there is no evidence of the disease on his admission to the hospital. I do not know whether splenomegaly alone can produce gastritis, but certainly gastritis can produce hematemesis, so I think we have to consider these two conditions, namely lymphoma and gastritis. Any other diagnosis would be mere guessing. In conclusion, since he had an enlarged spleen and a diagnosis of lymphosarcoma had been made on the mass removed from his right axilla, I must make lymphoma my primary diagnosis. I believe his bleeding came from the stomach and was most likely due to an acute gastritis.

DR. WYMAN RICHARDSON I think you have thrown out the diagnosis of thrombosis of the splenic vein too hastily. Why should he not have obstruction due to that or cirrhosis, and splenomegaly with gastric varices and hemorrhage from them?

DR. LINTON I think that is a possibility. The unusual thing to me about the whole affair from this point of view is that he had such severe pain with hematemesis. When a man has hematemesis from ruptured esophageal varices he usually does not have much pain. It was chiefly because of this I thought that his bleeding was not from varices.

DR. EDWARD B. BENEDICT Why had he not had perforation of the stomach?

DR. LINTON You do not see hemorrhage and perforation together.

DR. BENEDICT Not usually, but it is possible.

DR. LINTON Yes, but I have never happened to see it.

DR. FRANCIS T. HUNTER I never saw this man, but I do not believe there is much question but that he had lymphoma with infiltration of the stomach and probably a ruptured stomach and a ruptured spleen. He must have had a hole through the spleen, which was already infarcted, according to the story. I think you are going to find a lot of lesions in the left upper quadrant.

DR. LINTON An infarct is a good suggestion. Yet the white count is not in favor of lymphoma.

DR. HUNTER In lymphoma the white count can be anything.

CLINICAL DIAGNOSES

Lymphoblastoma, lymphocytic type.
Hematemesis

DR. LINTON'S DIAGNOSES

Lymphoma
Gastritis.
Hematemesis (from the stomach)

ANATOMICAL DIAGNOSES

Hodgkin's disease of spleen and retroperitoneal tissues

Infarction and ulceration of the spleen

Perforation of the stomach.

Fatal hemorrhage.

PATHOLOGICAL DISCUSSION

DR. MALLORY The postmortem examination showed a tremendously dilated stomach which was completely filled by a cast of blood clot over a foot in length. Unquestionably the hemorrhage was massive enough to be the immediate cause of death. On the lateral wall of the stomach near the cardia was a large jagged perforation which led into a corresponding hole in the spleen, which was several centimeters in depth. The spleen was greatly enlarged, weighing 1700 gm., and showed tumor nodules and multiple infarcts. Beneath the spleen in the region of the tail of the pancreas and throughout the retroperitoneal tissues was extensive tumor and this had infiltrated and completely occluded the splenic artery so that there was good reason for the infarction of the spleen. The mass had also infiltrated down as far as the left kidney which showed some invasion of the peripheral portion. Unquestionably the source of the terminal hemorrhage was the perforation of the stomach and bleeding from the spleen itself. What the mechanism of the perforation was, I feel less certain about. In the face of completely absent hydrochloric acid it is difficult to believe that it could have been a peptic ulcer, and the histology does not suggest it. I think it is more likely that the spleen became adherent to the stomach and that infarction of the spleen occurred and broke directly through the stomach wall. I should be inclined to trace it that way rather than from the stomach outward. We could discover no tumor in the stomach walls—only severe gastritis.

DR. MEANS There is a story of possible trauma ten or twelve days before death when he fell downstairs. I wonder if he injured his spleen at that time. A lymphomatous spleen is very easily traumatized. I remember one man with a huge leukemic spleen who squeezed it so hard one day that it ruptured and he died of hemorrhage. I wonder if he had a hematoma in the spleen in close approximation to the stomach.

DR. MALLORY I think that is possible. The lesion lay at the upper end of the spleen. The area was covered by the thoracic cage, however, so it could not be directly injured by trauma unless by contrecoup.

A PHYSICIAN Do we not have occasional

lymphomatous ulcers of the stomach with perforation and general peritonitis?

DR. MALLORY We have seen lymphomatous infiltration of the stomach with perforation, but here there is minimal evidence of involvement of the stomach itself. From the slides I cannot be certain there is any. The most surprising thing from the histological point of view is that the lesion was quite characteristic of Hodgkin's disease and in retrospect it is hard to believe that we could have called it lymphosarcoma. I wonder if we were not misquoted.

DR. MAURICE FREMONT-SMITH Why did it bleed so much if the splenic artery was occluded?

DR. MALLORY That is hard to answer, but massive hemorrhage is common following infarction and the presumption that a good deal of it had been retrograde from the veins seems to be the only explanation.

DR. GEORGE A. MARKS Was the splenic vein involved?

DR. MALLORY By pressure but not by tumor infiltration, as the artery was

PHARMACOTHERAPY

THE criticism is valid that, while clinical diagnosis has advanced remarkably in the past quarter of a century, progress in medical treatment is lagging. Pharmacology, the scientific basis of therapeutics, has come to be considered by many to be of little practical value, and a number of schools have gone so far as to abolish their pharmacological departments.

Pharmacology, as established by Schmiedeberg and his pupils, is essentially a science dealing with the effects of chemical and biologic agents on normal animals and on surviving organs. Due to such systematic investigations of old and new drugs, critique invaded therapeutics for the first time, with the result that the majority of previ-

ously used medications were eliminated as useless. But great though it was, this contribution of experimental pharmacology was to a large extent limited. Often unjustified conclusions regarding the treatment of disease in man were drawn from observations on normal animals. After a half century of this sort of analytic activity, it is natural that the field became somewhat sterile and ceased to draw able and inspired workers.

Recently, however, there has seemed to be justification for the optimistic belief that what is considered by many a vicious circle in the development of pharmacology is actually the beginning of the second circle of a spiral—a form that scientific progress often takes. Among the developments important to this expected renaissance of pharmacotherapy are the advances in quantitative chemical, physiological and immunological methods applicable to men, the increasing opportunities to induce disorders and diseases in animals and the close co-operation between groups of investigators in allied fields. These developments make it possible systematically to advance the findings of the laboratory to the treatment of diseased animals and, eventually, of men. As a result more important therapeutic discoveries have been made during the past decade than ever before—discoveries which have forever eliminated therapeutic nihilism in medicine. Progress in infectious diseases, in nutritional deficiencies, in dysfunction of the glands of internal secretion and in nervous disorders are but a few of the therapeutic triumphs.

It is essential to appreciate, however, that not pharmacological laboratories alone but all departments of physical, biological and clinical sciences have played their roles in these discoveries. For example, there are at present more than two hundred pharmacotherapeutic investigations in progress at Harvard University, scattered throughout its various scientific departments. Such widespread activity calls for helpfulness and co-ordination by a group representing the diversified interests involved. In the distant past, universities were institutions composed of groups of thinkers working in close association, and the

segregated departments of today are the result of the material and technical developments of the past century. But new interests that cut across a number of departments call once more for close personal association. It is significant, therefore, that President Conant has recently appointed a University Committee for Pharmacotherapy. It is hoped that, as a result of the activity of this committee, clinical and scientific interests will be brought closer together, pharmacotherapeutic investigations will be better guided, teaching of pharmacology and therapeutics will improve, post-graduate education in this diversified field will be fostered, and co-operation between the investigators in academic and industrial fields will be promoted.

Able students frequently enter surgery because they feel they can do more for the patient. The recent, rapid developments in pharmacotherapy should convince students that clinical medicine also offers great opportunities for treatment. Here there opens up a highly specialized field where physicians must use therapeutic agents which are often more effective and more dangerous than the scalpel. Pharmacotherapy may be considered by medical historians of the future as one of the most significant developments in the history of medicine in the twentieth century.

PATHOLOGICAL SERVICE FOR THE SMALL HOSPITAL

With the increasing complexity of diagnostic procedures, the wider recognition of the advantages that the pathological laboratory can afford the clinician and the higher standards for approved hospitals, there has been an increased demand for pathologists. So far as the large centers are concerned, this can be readily met, but in the small and relatively isolated hospitals, it is a very definite problem. Rarely is the size of the hospital large enough to support a full-time pathologist, and about the only feasible plan has been the grouping of a number of hospitals together to utilize the services of a single pathologist.

Recognizing that a number of the small hos-

pitals away from the large medical centers have difficulty in arranging for pathological service, the New England Pathological Society has established a committee with the hope of giving impartial advice to hospitals interested in establishing pathological laboratories and of bringing together competent men desiring positions and hospitals desiring pathologists. A letter in this issue of the *Journal* calls attention to the plan. The committee is now endeavoring to aid a group of three small hospitals with their laboratory problems.

Should the present plan work out successfully, it may point the way for a more effective utilization of the help that laboratory procedures can give in diagnosis and treatment.

MEDICAL EPONYM

BANTI'S DISEASE

Guido Banti (1852-1927), professor of pathological anatomy of the medical faculty of the University of Florence, Italy, published his first account of the disease which bears his name in *La semaine médicale* (14 318, 1894). It is entitled "La splénomégalie avec cirrhose du foie." The original Italian draft of this article appeared a month later in *Lo sperimentale, sezione biologica* (48 447-452, 1894), with due credit to the French journal. An English translation appeared in the English edition of *La semaine médicale* (2 364, 1894). The following quotation is from the English version.

In 1882, my attention was directed to the existence of a symptomatic and anatomic-pathological complex which, so far as I am aware, has never been described, and which may well be considered as a special kind of disease, namely, *splenomegaly with cirrhosis of the liver*.

The symptoms of the disease may be divided into three groups, corresponding to as many periods, viz. the *prae-ascitic* stage, the *ascitic* stage, and an *intermediate* stage.

The symptoms of the *prae-ascitic* stage are tumefaction of the spleen and anaemia.

In the cases with which I have had to deal, the *prae-ascitic* stage varied in duration from one year to four years and a half.

The *intermediate* stage is characterized by the appearance of dyspnoea, intestinal disorders, and sometimes haemorrhoids. This stage lasts a few months.

In the *ascitic* stage a liquid effusion takes place into the peritoneum. The anaemic symptoms become more and more marked, but the examination of the blood continues to give evidence of a normal number of leucocytes. This stage lasts from seven to eight months and ends in death.

OBITUARY

FREDERICK HENRY THOMPSON

1844 - 1939

In the December 21 issue of the *Journal* the death of Dr Frederick H Thompson, of Fitchburg, at the age of ninety five years and four months, was recorded.

He had the distinction of being the oldest living alumnus of Harvard Medical School, and also the oldest living member of the Massachusetts Medical Society, having joined in 1870. Even after giving up active participation in the affairs of the Society in 1920, he kept in touch with local medical affairs during the later years of his life.

He was well qualified for medical practice by graduation from Harvard Medical School and an internship at the Massachusetts General Hospital. After the completion of his hospital training, Lancaster welcomed Dr Thompson as the community doctor and physician to the Massachusetts Industrial School for Girls, where he established a reputation for sound practice.

His studies and service at the Massachusetts General Hospital under the direction of the prominent surgeons of that era had fostered an ambition to make surgery the major interest of his professional career, and in looking for greater opportunities, the growing city of Fitchburg presented attractive possibilities in this direction for which Lancaster could not compete, so after four years he moved to the larger community and soon became recognized as a valuable factor in the professional and civic life of that city. Practically all the important educational and cultural organizations of Fitchburg sought his support, which was freely given, although his major interest was always centered in medicine. Appointments to various official positions followed, among which were assistant surgeon and, later, surgeon of the 10th Regiment of the Massachusetts National Guard, secretary-treasurer and president of the Fitchburg Medical Society for Medical Improvement, orator, lecturer and president of the Worcester North District Medical Society, corresponding secretary of the Massachusetts Medico-Legal Society, two appointments as medical examiner of the third district of Worcester County, member of the Board of Directors, member of the United States Pension Examining Board, vice president and councilor of the Massachusetts Medical Society and delegate to the House of Delegates of the American Medical Association in 1911 and 1912. During the

World War, Dr Thompson served as chairman of the Selection Service Board of the 14th Massachusetts District, as captain surgeon of the Massachusetts National Guard and as a member of the Medical Reserve Corps. To this long list, other official city positions could be added.

Perhaps his longest and most concentrated interest was the Burbank Hospital. He was associated with its founding in 1891 and had served as a trustee and as a member of the staff, first as an active member and later as a surgical consultant. His influence in these positions was always of first importance in the growth of the hospital.

Here is presented a partial record of a busy and useful life of service which has inspired many tributes of affection and appreciation by his city and state. Those who were privileged to know him intimately profited by his sincerity and by his loyalty to high ideals and energy, which combined to establish qualities of leadership that brought success to his undertakings.

The history of Fitchburg will preserve the records of the accomplishments of this loyal and devoted citizen through all time, and his example will stand as an inspiration to those on whom his mantle has fallen.

W P B

MASSACHUSETTS MEDICAL SOCIETY

SHATTUCK LECTURE

The Shattuck Lecture will be given, as usual, following the annual dinner on May 21, and the Society has been extremely fortunate in obtaining Dr Ernest W Goodpasture as the speaker. The provisional title of the address is "Immunity to Virus Infections. Some theoretical and practical considerations," and Dr Goodpasture is eminently qualified to discuss the subject, since for many years he has been an outstanding contributor to the various problems associated with virus infections.

From 1915 to 1922, Dr Goodpasture was a member of the Department of Pathology at the Harvard Medical School, being assistant professor the last three years, and from 1922 to 1924 was director of the Singer Memorial Research Laboratory in Pittsburgh. In 1924 he was made professor of pathology at Vanderbilt University School of Medicine in Nashville, Tennessee, which position he now holds.

RAYMOND S. TITUS, M.D., *Secretary*
330 Dartmouth Street
Boston

PUERPERAL SEPSIS FOLLOWING LOW-FORCEPS DELIVERY

Mrs. J. R., a thirty-four-year-old primipara, entered the hospital on July 6, 1914, when approximately thirty-seven weeks pregnant, because of a systolic blood pressure of 190, edema and a large trace of albumin in the urine. She started in labor spontaneously on July 16 subsequent to premature rupture of the membranes, and was delivered of a stillborn child on July 17 by a simple low-forceps operation.

The family history was not recorded. The patient had had the usual children's diseases and one rather serious period of melancholia which lasted six weeks. Catamenia were regular, having begun at fourteen, with a twenty-eight-day cycle. The last period was October 23, 1913, making the expected date of confinement August 3.

Physical examination at the beginning of pregnancy showed a well-developed and nourished woman. The heart was not enlarged, there were no murmurs. The lungs were clear and resonant, there were no rales. The blood pressure was 104 systolic, 60 diastolic, where it remained until July 1, when it was 134 systolic, 70 diastolic. On July 6 the urine showed a large trace of albumin and the blood pressure was 180 systolic, 100 diastolic, there was a great deal of edema. She was sent to the hospital, kept in bed and placed on a restricted fluid intake. Prior to delivery, the signs of toxemia cleared up, the blood pressure dropping to 130 systolic, 90 diastolic, and the urine containing only a very small amount of albumin.

On the morning of July 19, two days after delivery, the temperature was 99.2°F, and the pulse 84, the afternoon temperature was 100.6, the pulse 100, the uterus was larger than normal but not tender. On July 20 the temperature was 99.6°F in the morning and 100.4 in the afternoon. On July 21 the temperature was 99.2°F in the morning and 100.2 in the afternoon. On July 22, five days after delivery, the patient had a chill, following which the temperature rose to 102.0°F, and the pulse to 96. In view of the fact that the uterus was still large, the cervix was dilated, with the escape of a considerable amount of

foul-smelling, thick, dark-brown lochia, and the uterus was curetted and washed out with a small amount of warm salt solution. Following this maneuver, the temperature rose to 103.0°F, and the pulse to 120. The following day, July 23, the temperature was 100.2°F in the morning and 101.0 in the afternoon. On July 25, two and a half days after the uterus had been curetted, the patient had a chill lasting ten minutes, the temperature rose to 104.0°F, and the pulse to 140. The following morning the temperature had dropped to 99.2°F, and the pulse to 90, but another chill sent the temperature to 104.0 and the pulse to 140. On July 27 she had a chill in the afternoon, with a temperature of 104.0°F and a pulse of 120.

The temperature continued to be of the picket fence type for about ten days, when it came down to normal and remained there. She was discharged on August 16, one month after delivery.

Comment. It is impossible to be sure that intrauterine manipulation following a temperature for several days was the direct cause of precipitating a minor infection into a serious one, nevertheless such was probably the case. The patient was much sicker after the uterus had been curetted and washed out than she had been before. No cultures of the uterus were taken, nor were any blood cultures, no blood studies were made. The handling of this case was typical of that in vogue twenty-five years ago. The presence of the persistent low-grade temperature immediately after delivery until the chill on the fifth day is definite evidence of uterine infection starting soon after delivery. Today uterine cultures and blood cultures would have been taken, ice would have been applied to the fundus, some form of ergot would have been given to stimulate uterine drainage, but the uterus would never have been invaded. However, the patient was treated entirely conservatively after the initial mistake. It is quite fair to infer that if the uterus had been left alone, convalescence would have been much shorter, uterine trauma undoubtedly spread the infection.

This case also illustrates the successful treatment of toxemia occurring rather precipitantly late in pregnancy. Rest in bed and a restricted fluid intake were the essence of the treatment.

REPORT OF THE COMMITTEE ON INDUSTRIAL HEALTH

HEALTH SERVICE IN INDUSTRY

An industrial medical service in order to justify its existence must accomplish the following objectives

- (1) It must by means of physical examinations assist

*A series of selected case histories by members of the section will be published weekly. Comments and questions by subscribers are solicited and will be discussed by members of the section.

the employment department in the placement of applicants and in the weeding out of the very few who may be unfit for employment.

(2) It must co-operate with the safety engineer in making safe the plant and all its machinery and processes so that they may not constitute a source of injury or disease to any employee.

(3) It must furnish early and efficient care of industrial injuries, having in mind the welfare of the employee, the easing of his pain and the bringing about of his early return to work and full earning capacity.

(4) It must make the employee's working hours safe by giving him good healthful surroundings, good medical advice and protection from others who may have defects or disease which would constitute a menace to him.

(5) It should provide, so far as it is within the province of industry reasonable protection from loss as a result of sickness or injury.

(6) It must co-operate with local public-health agencies, physicians and hospitals in carrying out the general community health program.

(7) It should maintain at all times strictly ethical and friendly relations with the family physicians of employees.

(8) It must be so conducted that the industrial physician always maintains with the employee the strictly confidential relation which traditionally exists between doctor and patient.

Health service in industry did not have its beginning in as comprehensive a program as this but even the least pretentious program today is attempting to live up to these requirements.

Facilities for the care of injuries today in our industrial plants are not considered adequate unless they are immediately available. A first-aid room with a nurse in charge may be adequate in some of the small plants but all cases requiring more than first aid should be cared for by a physician. The physician may be the family doctor or a physician employed by the plant. In the large factories the great number of daily treatments necessary call for the employment of a full-time doctor.

The first step in this program is concerned with the choice of healthy employees by means of physical examinations at the time of employment. This examination should accomplish the following ends: first, place the man on the job for which he is physically fitted; second, protect the person already employed from the entrance into the plant of others who might have transmittable disease or who by some serious physical defect might constitute a menace if given employment; third, the discovery of remediable defects and the giving of helpful advice aimed toward their correction.

The second requirement in the establishment of a well-rounded program, according to the standards enumerated above, has to do with the bringing about of safe working conditions. This is a work which can be carried out in any plant whether or not that plant has a medical department. The trained safety engineer has by his excellent work in so many of our industries built himself a lasting monument in the reduction of accidents and the saving of lives. It is probably no exaggeration to say that most operations have now been made so safe that the majority of accidents now occurring are due to the faulty human element involved. The injured workman or some careless fellow workman is frequently the cause of the accident. This

weakness must not be overlooked. The employees must be educated in safe practices in all their activities, and this educational process is a logical function of the medical department as well as of the safety department. Recounting of the many ways in which these safety measures have been consummated is not necessary now but some of the devices are worthy of mention. These are automatic brakes on revolving machinery guards over gears and moving parts, hand guards to prevent hands and fingers from entering the danger zone, hard toes for shoes to prevent injury from falling objects, automatic gates on elevators, exhaust ventilation for the removal of dust and fumes, establishment of safety zones by the efficient layout of traffic lanes, and many others just as important.

Frequent visits of inspection to all departments of the factory are essential to a successful health program of this type. The alert doctor can observe any infraction of the rules of safety and health and also at first hand see that his safety recommendations have been carried out.

Dust which contains silica in considerable quantity may constitute a hazard, and constant supervision of handling methods is necessary. Adequate exhaust ventilation and the use of respirators will as a rule prevent silicosis in the dusty trades, but only if someone makes it his job to see that these protective devices are used. There may be other hazards which cannot be guarded against by the methods above mentioned. Toxic materials and harmful dusts may constitute a definite hazard in some plants. It is the duty of physicians in these factories to know what materials are used and to determine their toxicity. It may in some instances be possible to substitute materials that are not toxic. When this is not possible, the physician must devise methods of protection. He should by careful periodic examination of individuals exposed discover the earliest signs of harmful effect from any of these substances. Lead and benzol are materials of this type. There are of course many others.

The third requirement in this health program provides for the immediate care of the injured employee and can best be carried out by having a hospital or dispensary centrally located in the factory and made easily accessible to all employees. This should be so equipped as to be capable of caring for the most severe injury so far as first aid is concerned, and also for the continued care of all ambulatory cases. It is assumed of course that these treatments are made under adequate medical supervision. This medical supervision may be by a local practicing physician spending part time in the plant or by a physician devoting full time to the work.

The industrial physician will keep up to date on all the latest developments of medicine which pertain to his plant. Also the wise industrial physician will provide himself with a goodly number of consultants and hospitals in whose hands he can place those cases which he is not equipped to handle. In choosing these consultants and hospitals he will invariably pick the best, and as a consequence the industrial employee is provided with the finest medical service obtainable. This type of service should be provided by industry not from the standpoint of good economics alone, but from a real interest in the welfare of the workers. Most industrial workers appreciate this fact and have come to look upon such service as a matter of right. They enjoy these benefits and are appreciative of them.

The medical and surgical care of these injuries calls for a thorough knowledge of the plant set-up on the part of the physician who is responsible for this service. He must know how the injury occurred in order to assist the safety department to guard against its recurrence.

He must know the physical requirements of each injured employee's job so that he may return him to productive work as soon as he is able to do so. Much economic loss may be prevented if he does this part of his job well.

The fifth step of the program has to do with protection from financial loss due to sickness and injury. It is not very far back to the time when the worker was not compensated for his injuries unless they were due to neglect on the part of the employer, and then it was often necessary for him to sue at common law in order to obtain compensation. The advent of the Workmen's Compensation Law and its acceptance by most industries have eliminated that trouble, and now employees are usually compensated without litigation, regardless of who is to blame for the injury.

There is much more time lost from work because of non-industrial sickness and non-industrial accident than as a result of industrial accidents. This also calls for some type of protection for the employee against financial loss. Mutual benefit plans, non-contributory benefit plans entirely financed by the employer and contributory group-insurance plans are those commonly resorted to at present. Mutual benefit plans are functioning well in some plants and may be the plan of choice for a particular group. This plan has the advantage of giving the employees a direct interest in the management of it. A contributory plan, such as is furnished by group-health and accident insurance, fulfills the requirements and is not apt to be discontinued because of lack of funds to carry it on. In this type of insurance the employer can still share part of the cost. A popular group-insurance plan today provides weekly indemnity in the event of sickness or non-industrial accident, usually for a maximum period of thirteen weeks for any one disability. There is a waiting period of one week before benefits begin, so that no disability short of eight days receives payment. A life insurance policy may be issued in combination with the weekly indemnity. This type is usually underwritten by an insurance company but in many cases the administration of it is a function of the medical department.

Any of these plans call for investigation of absenteeism by the medical department. Probably the best investigator of absentees is a trained nurse who is usually well known to all employees and is well received when she visits their homes. Being well trained to recognize illness and need, she is able to help in obtaining proper medical assistance for the patient by co-operating with the family physician or other interested agencies. The majority of employees accept this investigation at its true value and desire its continuance.

There can be no doubt in the minds of anyone as to the value of such insurance. Those who are close to the factory worker and his financial problems know what a staggering blow is dealt by an extended absence from work, especially when the disabled one is the head of a family. Not only has he the expense of medical care but he must find in addition a way to provide his family with the necessities of life while he is cut off from his earnings. Provision must be made to reimburse, in part at least, the disabled employee. The question is often asked whether or not employees take advantage of a plan like this to take vacations with pay. It is true that an occasional one may malingering, but there is nothing gained by penalizing the majority for the misdemeanors of the few. All plans have flaws and if the opportunity to malingering is the flaw in this type of insurance it still fulfills its purpose. It should be continued until something better offers.

The sixth requirement of the medical department in industry is co-operation with existing outside agencies,

family physicians, boards of health and welfare organizations. Though the physician is doing much for the worker through industrial health programs he has not replaced these other agencies. He has merely augmented their services and is not self-sufficient. The family doctor just as necessary to employees to whom this service is available as he was before. He is even more necessary, because industrial medical service has educated employees to take better care of their health and has encouraged them to seek the aid of their family doctors for conditions which they had been accustomed to ignore.

The industrial physician has an opportunity to do a real service to the community in his work along the lines of preventive medical care. The early discovery of communicable disease and the use of all known methods for its control are two of the principal functions of an industrial medical department. In protecting employees from exposure to them he is also protecting the community. The next great step in the fight against tuberculosis may possibly be made through the co-operation of industry and the departments of public health. Great work has been done in the young age groups in the public schools but less among employed groups by public-health agencies. The doctors in industry can be of help by adopting in the factories the same methods which have accomplished so much among the young groups. Through their industrial clinics they should be able to assist greatly in the continuation of this program.

This in general is the aim of most industrial medical departments, some giving service beyond that set forth here and some giving much less. The industrial physicians who are responsible for this service, however, must be well trained and especially familiar with occupational hazards and the general practice of safety and must not lose sight of the fact that no matter how large their organizations may be the confidential relation of physician and patient must be maintained.

W. IRVING CLARK, M.D., *Chairman*,
LOUIS R. DANIELS, M.D.,
NOEL G. MONROE, M.D.,
HALSTEAD MURRAY, M.D.

DEATHS

HILLARD—JAMES P. HILLARD, M.D., of Springfield, died January 29. He was in his sixty-third year.

Born in Fall River, he received his degree from Jefferson Medical College of Philadelphia in 1903, and had practiced in Springfield for thirty-seven years. Dr. Hillard was examiner for the Bureau of Pensions, Department of the Interior, and for the Travelers Insurance Company. For thirty-three years he was medical inspector in the public schools of Springfield and had served as physician for the Police and Fire departments.

He was a member of the Massachusetts Medical Society and the American Medical Association.

His widow, a brother, a niece and a nephew survive him.

KITTREDGE—JOSEPH KITTREDGE, M.D., of North Andover, died January 31. He was in his eighty-third year.

Dr. Kittredge received his degree from the Harvard Medical School in 1880 and practiced medicine in Brookline and Marblehead until 1918 when he retired to run his own sanatorium. He was the eighth in a nine-generation family of doctors.

He was a member of the Massachusetts Medical Society and the American Medical Association.

His widow a brother two sons and a daughter Dr Edwina Kittredge Newberry survive him.

PAYNE—JAMES H. PAYNE M.D., of Allston, died January 31. He was in his seventy-eight year.

Born in Boston he attended Harvard University and received his degree from Harvard Medical School in 1889. He studied in London and Paris, and practiced medicine in Boston for eight years before entering the naval corps.

Dr Payne was a fellow of the Massachusetts Medical Society and the American Medical Association and held memberships in the Association of Military Surgeons of the United States and the British Medical Association.

His widow, a son and a daughter survive him.

PRATT—DAVID D. PRATT M.D. of New Bedford died January 29. He was in his sixty-first year.

Born in Wisconsin, he attended Dartmouth College and received his degree from the Harvard Medical School in 1906.

Dr Pratt was a fellow of the Massachusetts Medical Society the American Medical Association and the American College of Surgeons. He was also a member of the New Bedford Medical Society.

His daughter a son, a brother and a niece survive him.

WHITESIDE—GEORGE S. WHITESIDE, M.D., of New York City died January 29. He was in his sixty-eighth year.

Born in Boston he attended Harvard University and received his degree from Harvard Medical School in 1897. He was formerly examining physician for several insurance companies and had served as surgeon for the Winchester Arms Company of New Haven.

Dr Whiteside was a former member of the Massachusetts Medical Society and was a fellow of the American Medical Association and the American College of Surgeons. Formerly he was secretary of the Harvard Medical Alumni Association.

His widow two sons and a daughter survive him.

CORRESPONDENCE

PATHOLOGICAL SERVICE FOR THE SMALL HOSPITAL

To the Editor Recently a group of small hospitals near Boston requested the New England Pathological Society to aid them in obtaining the services of a pathologist. This was the first time in its history that the society had been directly approached by a hospital for such a purpose, and it was believed that perhaps this was the beginning of an opportunity for the society to act as an impartial adviser to hospitals with respect to their pathological services only of course when directly solicited. The society has therefore appointed a committee the members of which will act as consultants and as a clearing house to help both hospitals and pathologists.

Any request for information should be forwarded to the secretary

BENJAMIN CASTLEMAN Secretary
New England Pathological Society

Massachusetts General Hospital
Boston.

A SURE CURE

To the Editor Below is a copy of an item taken from Middlebrook's *New England Almanac* for the year 1830

which I thought might be of interest to readers of the *Journal*

An exchange says Every little while we read in the papers of someone who has stuck a rusty nail in his foot, or knee, or hand or some other portion of his body and that lockjaw resulted therefrom, of which the patient died. If every person was aware of a perfect remedy for all such wounds, and would apply it, then all such reports must cease. Yet all these wounds can be healed. The remedy is simple, almost always on hand and can be applied by anyone, and what is better it is infallible. It is simply to smoke the wound that is inflamed with burning wool or woollen cloth. Twenty minutes in the smoke of wool will take the pain out of the worst wound, repeated two or three times it will allay the worst cases of inflammation arising from a wound.

CHARLES W. ROBERTSON M.D.

Amherst, Mass.

RESTORATION OF LICENSE

To the Editor This is to inform you that in accordance with the vote of the Board of Registration in Medicine, the license of Dr Rafael R. Garcia of Agawam revoked on September 29 1938 was restored on January 18, 1940

STEPHEN RUSHMORE M.D., Secretary

State House,
Boston.

NOTICES

ANNOUNCEMENTS

JACOB KAMINSKY M.D. announces the opening of an office at 891 Massachusetts Avenue, Cambridge.

HYMAN H. SHUMAN M.D. announces the opening of an office at 107 Prichard Street, Fitchburg

BOSTON CITY HOSPITAL

The monthly clinicopathological conference will be held at the Boston City Hospital on Wednesday February 14 at 12 o'clock noon, in the Pathological Amphitheater

PETER BENT BRIGHAM HOSPITAL

A joint medical and surgical clinic at the Peter Bent Brigham Hospital will be held on Wednesday February 14 from 2 to 4 p.m. Drs. Elliott C. Cutler and Soma Weiss will speak on "Nervousness."

BOSTON SOCIETY OF PSYCHIATRY AND NEUROLOGY

The next meeting of the Boston Society of Psychiatry and Neurology will be held at the Boston Medical Library on Thursday evening February 15 at 8 15

PROGRAM

A Phantasy Gratified by a Suicidal Act. Dr Ives Hendrick.

Prefrontal Lobotomy in Two Patients with Agitated Depression With therapeutic evaluation and further reference to prefrontal-lobe function. Drs. W. J. Mixter K. J. Tillotson and David Wiers.

HARVARD MEDICAL SOCIETY

The next meeting of the Harvard Medical Society will be held on Tuesday, February 13, in the amphitheater of the Peter Bent Brigham Hospital (Shattuck Street entrance), at 8 15 p.m.

PROGRAM

Presentation of cases

The Application of Medical Science to the Administration of Justice. Dr Alan R. Moritz.

Medical students and physicians are cordially invited to attend.

NU SIGMA NU LECTURE

The annual lecture sponsored by the Harvard chapter of Nu Sigma Nu will be given in Building E of the Harvard Medical School on Thursday, February 29, at 5 00 p.m. Dr Donald D Van Slyke, of the Rockefeller Institute, will speak, his subject being "Renal Physiology"

LAWRENCE CANCER CLINIC

The regular Lawrence Cancer Clinic, to be held at Lawrence General Hospital, 1 Garden Street, Lawrence, on Tuesday, February 20, at 10 00 a.m., will be a demonstration and teaching clinic for physicians, with Channing C Simmons, M.D., of Boston, as consultant. Physicians of the north half of Essex County are invited to accompany any of their patients whom they desire to have this service or to send them with a note. A report will be returned to every physician who sends a patient. The service is gratis. Any physician is welcome to attend the clinic.

SUFFOLK CENSORS' MEETING

The censors of the Suffolk District Medical Society will meet for the examination of candidates at the Boston Medical Library, 8 Fenway, Boston, on Thursday, May 2, at 4 00 p.m.

Candidates should make personal application to the secretary and present their medical diplomas at least six weeks before examination (if graduates of foreign medical schools or schools not on the list recognized by the Council, at least eight weeks before)

WORCESTER DISTRICT MEDICAL SOCIETY

The next meeting of the Worcester District Medical Society will be held at the Worcester State Hospital, Worcester, on Wednesday, February 14. Dinner will be served by the hospital at 6 30 p.m. Following dinner there will be a business and scientific meeting. Dr William Malamud will present a paper on "The Treatment of the Neuroses in General Practice." Saul Rosenzweig will speak on "Experimental Neuroses," and the talk will be illustrated by Maier and Glazer's movie film which was awarded a prize by the American Association for the Advancement of Science.

NEW ENGLAND PATHOLOGICAL SOCIETY

The next meeting of the New England Pathological Society will be held on Thursday evening, February 15, at 8 00 at the Tufts College Medical School, 416 Huntington Avenue, Boston.

PROGRAM

Pathological Observations in Simmonds' Disease. Dr R. C. Wadsworth.

Immediate Wheal and Erythema Type Reactions to Simple Chemical Substances. Dr John Jacobs.

Pathological Findings in Leukoerythroblastic Anemia. Dr S. B. Thorson.

Primary Tumor of the Heart. Dr Harold Wood.

The pathological demonstrations will be available at 7 00 p.m. There will be a short business meeting followed by a collation.

Physicians and students are cordially invited to attend.

UNITED STATES MARINE HOSPITAL

The staff meeting of the United States Marine Hospital, Chelsea, will be held at "The Hut," on Friday afternoon, February 14, at 3 00. Dr John W. Strieder will be the guest speaker, his subject being "Clinical Aspects of Bronchogenic Carcinoma."

HATHERLY MEDICAL CLUB

There will be a meeting of the Hatherly Medical Club at the Toll House on Wednesday afternoon, February 14, at 3 00. Dr William E. Browne will be the guest speaker, his subject being "Diagnosis and Treatment of Nerve and Tendon Injuries to the Hand."

VAN METER PRIZE AWARD

The American Association for the Study of Goiter again offers the Van Meter Prize Award of three hundred dollars and two honorable mentions for the best essays submitted concerning original work on problems related to the thyroid gland. The award will be made at the annual meeting of the association which will be held at Rochester, Minnesota, on April 15, 16 and 17, providing essays of sufficient merit are presented in competition.

The competing essays may cover either clinical or research investigations, should not exceed three thousand words in length and must be presented in English, a typewritten double-spaced copy should be sent to the corresponding secretary, Dr W. Blair Mosser, 133 Biddle Street, Kane, Pennsylvania, not later than March 15.

A place will be reserved on the program of the annual meeting for presentation of the prize essay by the author, if it is possible for him to attend. The essay will be published in the *Proceedings* of the Association. This will not prevent its further publication, however, in any journal selected by the author.

ALUMNI DAY, NEW YORK UNIVERSITY COLLEGE OF MEDICINE

Alumni Day of New York University College of Medicine will be held on February 22. Following opening remarks by Dr James S. Smith, president of the Alumni Association, a series of formal lectures on "Modern Aspects of Preventive Medicine" will be presented at the medical school during the morning and afternoon sessions. Luncheon will be served at the school at 1 00 p.m. Dean McEwen will be host at an informal reception in the dean's office at 5 00 p.m.

SOCIETY MEETINGS AND CONFERENCES

CALENDAR OF BOSTON DISTRICT FOR THE WEEK BEGINNING SUNDAY FEBRUARY 11

SATURDAY FEBRUARY 11

- 4 p.m. Cancer. Dr. Grantley W. Taylor. Free public lecture. Harvard Medical School, amphitheater of Building D.
- 4 p.m. Cancer of the Stomach. Dr. Marshall K. Bartlett. Illustrated, public, health lecture. Faulkner Hospital auditorium.

TUESDAY FEBRUARY 13

- 9-10 a.m. Hospital case presentation. Dr. S. J. Thabauer. Joseph H. Pratt Diagnostic Hospital.
- 8:15 p.m. The Obstetric Pelvis. Dr. W. E. Caldwell. Journal Club. Boston Lying-in Hospital.
- 8:15 p.m. The Application of Medical Science to the Administration of Justice. Dr. Alan R. Moritz. Harvard Medical Society. Peter Bent Brigham Hospital amphitheater (Rushmore Street entrance).

WEDNESDAY FEBRUARY 14

- 9-10 a.m. Clinicopathological conference. Dr. C. S. Keefer. Joseph H. Pratt Diagnostic Hospital.
- 12 m. Boston City Hospital, monthly clinicopathological conference.
- 3-4 p.m. Nervousness. Drs. Elliott C. Cutler and Soma Weiss. Peter Bent Brigham Hospital.

THURSDAY FEBRUARY 15

- 8 p.m. New England Pathological Society. Tufts College Medical School.
- 8:15 p.m. Boston Society of Psychiatry and Neurology. Boston Medical Library.

FRIDAY FEBRUARY 16

- 9-10 a.m. Some Observations on Pituitary Adenoma. Dr. M. C. Sommers. Joseph H. Pratt Diagnostic Hospital.

SATURDAY FEBRUARY 17

- 9-10 a.m. Hospital case presentation. Dr. Thannhauser. Joseph H. Pratt Diagnostic Hospital.

DISTRICT MEDICAL SOCIETIES

ESSEX SOUTH

- FEBRUARY 14—Cough, Sputum, Hemoptysis—How shall they be investigated? Dr. Reeve H. Bess. Essex Sanatorium, Middleton.

- MARCH 6—Experimental and Clinical Consideration of Sulfanilamide Treatment of Hemolytic Streptococcus Infections. Dr. Champ Lyons. Lynn Hospital, Lynn.

- APRIL 3—Addison Olcott Hospital, Gloucester.

- MAY 8—Annual meeting. Salem Country Club, Peabody.

FRANKLIN

- MARCH 12—Franklin County Hospital. Greenfield.

- MAY 14—Franklin County Hospital, Greenfield.

HAMPSHIRE

- MARCH 13

- MAY 8.

- Meetings are held at 11:30 a.m. at the Coolidge Dickinson Hospital, Northampton.

MIDDLESEX EAST

- MARCH 20.

- MAY 15.

- Meetings are held at 12:15 p.m. at the Unicorn Country Club, Stoughton.

MIDDLESEX NORTH

- APRIL 24

- JULY 31

- OCTOBER 30.

NORFOLK SOUTH

- MARCH 7

- APRIL 4

- MAY 2.

- All meetings, with the exception of one which is usually held at the Quincy City Hospital are held at the Norfolk County Hospital in South Braintree, at 12 o'clock noon.

PLYMOUTH

- MARCH 21—Goodard Hospital, Brockton.

- APRIL 18—State Farm.

- MAY 16—Lakerville Sanatorium, Lakerville.

SUFFOLK

- MARCH 27—Scientific meeting. Symposium on Ulcerative Colitis and Diarrhea. Under the direction of Dr. Chester M. Jones.

- APRIL 24—Annual meeting in conjunction with the Boston Medical Library. Election of officers. Program and speakers to be announced later.

- MAY 2—Censors meeting. Page 244.

WORCESTER

- FEBRUARY 14—Page 244.

- MARCH 13—Worcester Memorial Hospital.

- APRIL 10—Worcester Hahnemann Hospital.

- MAY 8—Worcester County Club.

- Each meeting begins with a dinner at 6:30 p.m. and is followed by a business and scientific meeting.

BOOK REVIEWS

Psychopathic States D K Henderson. 178 pp New York W W Norton & Co, Inc., 1939 \$2 00

The problem of that heterogeneous and ill-defined psychiatric group known as the constitutional psychopathic inferior is of importance, inasmuch as the conduct of the members of this group is often such as to bring them into conflict with the law and consequently involves psychiatric expert testimony, and it is this problem that Dr Henderson, the eminent British psychiatrist, considers. His discussion has charm and wisdom, and he comes to the predestined conclusions that much more research and more exact studies must be done before the conditions described under this widespread term can be understood and socially or psychiatrically treated.

The constitutional psychopathic inferiors constitute a group in which the conduct disorder and general psychological reactions run the gamut from the liar-swindler type to the less numerous and more bizarre individuals in whose life homosexuality, rape and ferocious immorality appear, and whose responsibility consequently must be passed on. In between these extremes of conduct, one meets the chronic alcoholic, the drug addict, the ne'er-do-well and those unemployable individuals whose difficulty is not due to physical disease but to a mental state which cannot be classified as psychotic or neurotic but comes down to instability of personality of one type or another.

It will be seen that there can be no sharp differentiation between the normal and these individuals. Homosexuality and other abnormal sexual manifestations are widespread and involve individuals whose lives otherwise run not only along normal lines but sometimes along super-normal ones. Similarly, alcoholism cannot be linked with social or psychological inferiority since among the alcoholics one often finds the geniuses of the race.

Indeed, Dr Henderson brings up the question which for so long a time has been a focus of human attention, — whether or not genius is a psychopathic trait, — to which Lombroso, Nordau and Henderson, as well as many others, have answered "Yes," and other workers, especially the eugenicists, "No." As a matter of fact, generalizations can no more be made about the trait of genius than about the qualities of the so-called "normal" individual, since there are many kinds of genius, and high ability of whatever type may be linked to all kinds of qualities of character and personality. The personality of man is not a harmonious composition, no more than his body is. Character is largely a mosaic in which there is often a juxtaposition of the most incongruous qualities. A Bacon may be a great philosopher and a wise lord chancellor, but he may also be a bribe taker and a foolish thief.

Henderson definitely indicates all this. The point of view he expresses is pragmatic and clinical, but he has as yet no solution, either legally or otherwise, for the problems inherent in the term, constitutional psychopathic inferiority, and in the types of individuals classed as suffering from

it. However, he makes the important observation that the law in England has commenced to modify its attitude toward this group, that the concept of limited responsibility is appearing in the court decisions, and that the all-or-none theory of responsibility is passing away, as indeed it should, since there are degrees and shades of responsibility for crime as there are degrees and shades of all human qualities and attributes.

A deeper problem has preoccupied the reviewer for many years. It is assumed that adaptation to whatever happens is the test of normality, and in a certain sense this is true. But human society has built up extraordinary social mechanisms to which the individual must adapt himself, furthermore, it has built up systems of reward for certain types of personality and punishment for others. There is nothing in any candid view of society which indicates that it has shown much wisdom in the selection of either the types it rewards or the types it punishes. Thus, the acquisitive type of human being is over-rewarded. The individual who sacrifices biological necessities, such as reproduction, often has a social advantage over the individual who reproduces freely, as from a biological point of view he should. The person who sacrifices certain social trends in his nature, such as friendliness and generosity, often succeeds, while the individual who expresses these qualities in his life may become a social failure, and so forth. There may be a psychopathic society to which normal individuals cannot adapt themselves and to which certain abnormal individuals are able to adapt themselves. It is not proved that either social success or failure is necessarily a criterion of essential normality or abnormality, or indeed of personal worth or worthlessness.

Midwifery By ten teachers, under the direction of Clifford White. Edited by Comyns Berkeley, Clifford White and Frank Cook. Sixth edition. 676 pp Baltimore William Wood & Co, 1938 \$6 00

This sixth edition is a textbook on obstetrics by ten English obstetricians. The book is written primarily for English students preparing for their final examinations. It has little value from the American standpoint except for the purpose of comparing English methods with those practiced in America. As a reference book it is of value.

Tests for Mental Development. A complete scale for individual examination F Kuhlmann. 314 pp Minneapolis, Nashville, Philadelphia Educational Publishers, Inc., 1939 \$2 00

The author of this book is a well known authority on the subject of mental tests. He presents, for the specialist in the field of psychology, a new scale of tests, based on the Heims mental-growth curve. Practically none of the original Binet tests are used. Some from the author's previous revisions of the Binet scale of 1912 and 1922 and from the Kuhlmann-Anderson group tests are included in modified form. The rest are derived from other sources. The new scale seems to remove some of the disadvantages of the Binet type of scale. The application of these tests in the way that they are intended to be used, however, requires a long period of training and familiarity with the general scope of mental tests.

Workers in the field of psychology will find some of the author's suggestions to be of interest, — for example, his recommendation that the "personal constant" of Heims be used in place of the IQ as a measure of intelligence, — but it is doubtful that the new scale will be of value in the hands of the medical man.

CLINICAL MEASURES IN THE CONTROL OF SYPHILIS*

R A VONDERLEHR, MD†

WASHINGTON, DISTRICT OF COLUMBIA

EVERY experienced worker in the field of public health knows that teamwork is one of the most important prerequisites for success. With most of the acute communicable diseases, the teamwork involves chiefly the members of the health department because modern preventive measures have become so highly successful. This is not true, however, with the control of syphilis. The public-health campaign against this disease requires not alone the well-co-ordinated work of members of the health department but the active assistance of the medical profession as well. Control through prevention is the slogan in the acute communicable-disease campaign. Control through treatment is the slogan in the syphilis campaign. In the latter, the major emphasis is on treatment and the physician in general practice. Success in the control of syphilis will therefore be as much a contribution of the private physician as of the health officer.

The more important clinical measures of value in the present campaign will be considered in this paper. Among them are the effective utilization of the serological blood test and the modern treatment schemes for early and latent syphilis and for syphilis in pregnancy.

THE SEROLOGICAL TEST

Studies in the United States by the Committee on Evaluation of Serodiagnostic Tests for Syphilis have disclosed that the serological blood test is one of the most efficient of all laboratory procedures in use at the present time. The work of this committee has been noteworthy because it has been possible, through its activities conducted in co-operation with leading serologists and the several state health departments, to show very marked improvement in serological-test performance during the last few years.

In 1935 the results of the first evaluation of the

original serological tests and modifications used in the United States were published. This and subsequent investigations have proved that modern serological tests properly performed will detect from 80 to 90 per cent of syphilitic patients regardless of the stage of the disease and whether previous treatment has been given. The five serological tests regarded as satisfactory in this country have given on an average less than 0.5 per cent false positive results when performed by the originators.

But the following year a study of the efficiency of performance of these same serological tests for syphilis in state laboratories indicated that work in such laboratories did not in each instance have the same degree of excellence as was exhibited in the laboratories of the originating serologists.

A series of studies of efficiency of performance of serological tests in state laboratories, and a voluntary but intensive advisory program regarding technique, have yielded year by year very marked improvement. Indeed, during the last study by the committee, it was agreed that the character of the work in ten state laboratories was on such a high plane that it was necessary to determine the efficiency of their performance only biennially.

Certain basic principles have been described to which laboratories in general should adhere if the character of serological work performed in them is to be efficient. These basic principles were freely discussed during the Assembly of Laboratory Directors and Serologists held at Hot Springs National Park, Arkansas, October 21 and 22, 1938. Briefly, they consist of an intralaboratory check, using two or more serological techniques on a comparative basis, interlaboratory checks in which one laboratory compares the results of its serological-test performance with those of another laboratory known to be reliable, and a comparison of the serological results against known clinical diagnoses on specimens obtained from a selected group of nonsyphilitic persons and from syphilitic patients.

*Read at the annual meeting of the New Hampshire Medical Society, Manchester, June 9, 1939. From the Division of Venereal Diseases, United States Public Health Service, Washington, District of Columbia.

†Assistant surgeon general, United States Public Health Service, Washington, District of Columbia.

in a first-class clinic. The last is the most important of the three principles. In addition, laboratory directors should hold periodic technical consultation with expert serologists regarding the performance of tests in routine use. If laboratories serving the medical profession are not conducting comparative studies of this kind and seeking expert consultation, the physician in private practice should demand that they do so.

INTERPRETATION OF SEROLOGICAL TESTS

Only three terms should be used in reporting reactions to qualitative serological tests to the physician in general practice—positive, doubtful and negative. The serologist should learn, with such advisory assistance as he may require, to determine as exactly as possible the different degrees of complement fixation or flocculation which are reported as positive or doubtful by the originator of the test he is performing. A negative report naturally indicates no fixation of complement or no flocculation.

In the temperate zone a positive report is almost invariably indicative of syphilis if the possibility of administrative laboratory error is excluded. The diseases which may give false positive reports are mostly tropical, and except for malaria are relatively rare in the United States. A false positive reaction to a test for syphilis occurs in malarial fever only during the clinically active stage of the disease, it returns to negative when the patient recovers.

A single unsupported positive report should not be accepted as evidence of syphilis regardless of the efficiency of the laboratory from which it is received. Technical errors are apt to happen in any laboratory, no matter how well conducted, and in the absence of a definite history or physical evidence of syphilis a diagnosis should never be made until at least two tests, performed on specimens taken at different times, are reported as fully positive. Doubtful reports only indicate that the laboratory technician has been unable to state whether complement fixation or flocculation has occurred. The doubtful report is a request from the laboratory worker that a second specimen be sent to him for examination. If there are no clinical manifestations of syphilis present, a negative reaction must be considered as strongly presumptive evidence that syphilis is not present. On the other hand, if there are suspicious lesions, a negative reaction may be meaningless, and the physician must apply other special examinations before making his diagnosis.

Serological tests for syphilis should be utilized by physicians whenever a physical examination is done. From the standpoint of detecting unrecog-

nized disease, serological tests are more efficient than routine urinalyses, and cost very little more when done in large numbers. Serological blood tests should be a part of the examination of all seriously ill patients, all pregnant women, applicants for jobs and employees in industry and both applicants for marriage licenses.

It is surprising that a few health officers and physicians have objected to the widespread use of the serological blood test to discover syphilis. Laboratory tests are among the most important measures in detecting communicable diseases in public-health practice. The control of hookworm disease and malarial fever would have been much more difficult had not thorough laboratory studies of the feces and blood respectively been conducted in surveys of large population groups. The critical observer of public-health measures is impressed with the fact that the routine laboratory test is one of the most effective and economic methods of case finding when the prevalence of a disease assumes such proportions as syphilis has attained.

New Hampshire is to be congratulated on its early enactment of the law requiring a premarital medical examination including the serologic blood test in order to prevent the transmission of syphilis in marriage. Persons contemplating matrimony constitute a vitally important group from public-health point of view. Approximately 1 per cent of the many hundreds of thousands of people who acquire syphilis every year are less than thirty years of age. Eighty-five per cent of the brides and 65 per cent of the grooms come from this large age group.

The American Social Hygiene Association has recently published a survey of the first seven states which have had premarital laws in operation for a period sufficiently long to give data indicative of their effectiveness. The survey shows that over 225,000 applicants for marriage licenses have been examined in these states, and of them, 3300 were found to have syphilis, the proportion being about the same among men and women. This prevalence rate is in almost exact agreement with estimates previously made by the Public Health Service.

The critical student is convinced that premarital legislation is effective in controlling the conjugal and prenatal transmission of syphilis. He is also convinced that the public demand such laws, and expects the medical and public health profession to develop the necessary measures to enforce them properly.

TREATMENT OF EARLY SYPHILIS

The aim of the treatment of early syphilis is primarily the prevention of the transmission of

the disease, through treatment, and secondarily the recovery of the individual patient. Both laboratory data and more slowly accumulated evidence based upon clinical experience show that radical and complete cure is possible by the correct scheme of treatment. Control of infectiousness, limited largely to the primary, secondary and relapse manifestations of the first two years, is the important public-health attainment of modern treatment.

Let us examine the evidence which is available with reference to these two points in the studies of the Co-operative Clinical Group. In an analysis of the records of 3244 patients with early syphilis under observation for a period of six months or more, it was found that eight out of every ten who had a communicable relapse had received less than fifteen doses of one of the arsphenamines. Thirty-five per cent of these patients with communicable relapse had received less than five doses of an arsphenamine. Indeed, the frequency of communicable relapse was in indirect ratio to the amount of treatment received, particularly arsenical therapy.

Additional data obtained from these studies indicate that the critical time for treatment of the syphilitic patient, in order to prevent the spread of syphilis, is during the first two years of the infection. In the first six months, 45 per cent of all infectious relapses occur, by the end of the first year 74 per cent, and by the end of the second year, 91 per cent.

Treatment of the patient and not of the serological blood reaction is recognized today as one of the cardinal principles of anti-syphilitic therapy. This principle must be impressed upon patients by teaching them that treatment by schedule is the prerequisite to recovery. The serological blood test, when properly used during the administration of treatment, does, however, give valuable prognostic information to the attending physician.

Studies of the Co-operative Clinical Group have established that the failure of the reaction to reverse from positive to negative is more a matter of how treatment is given than of the total amount administered. Regular treatment with arsphenamine and heavy metals, especially in the first three months of the disease, brings about the greatest number of serological reversals. Under the continuous alternating scheme recommended by the Public Health Service, only 25 per cent of the patients whose serological reactions became negative within the first year of the disease developed a communicable relapse. This figure compares with 8.2 per cent of those receiving intermittent treatment with planned rest periods and 12.8

per cent of those non-co-operative patients who came in irregularly for treatment.

It has been found that in more than 90 per cent of the patients beginning treatment in the seronegative primary stage of syphilis, a satisfactory result is attained, a fact which continued observation indicates is tantamount to recovery. When treatment is given by the continuous alternating scheme, beginning at any time during the first year of the disease, recovery may be expected in an average of approximately 80 per cent of the patients.

The evidence which has been accumulated proves that the modern system of treatment for early syphilis must be continuous. It must employ an arsphenamine and preferably a bismuth preparation, the latter intramuscularly. It must include not less than twenty injections of both the arsphenamine and bismuth preparations in order to prevent the transmission of the disease, and not less than thirty injections of both arsphenamine and bismuth preparations in order to secure the ultimate recovery of the patient. The continuous alternating scheme of the Co-operative Clinical Group and the Public Health Service provides for the administration of thirty doses of one of the arsphenamines and forty doses of one of the bismuth preparations administered week by week, series of injections of the arsphenamines and of bismuth alternating over a period of seventy weeks. The blood should be tested at the beginning and end of each series of arsphenamine injections, and the patient warned that negative reports have no significance as an indication of recovery. Weakly positive reports following a negative should be taken as seriously as strong relapsing positives, since experience has shown that the former frequently are an omen of imminent clinical relapse. A spinal fluid examination, including a quantitatively titrated Wassermann test, cell count, protein estimation and colloidal gold test, should be made before the end of the several series of arsphenamine treatments.

PREVENTION OF SYPHILIS IN PREGNANCY THROUGH TREATMENT

The second great opportunity to prevent the transmission of syphilis comes to the physician when the syphilitic pregnant woman presents herself for prenatal care. With early and adequate treatment during pregnancy, the prognosis is most favorable for the birth of a healthy infant. Ten or more injections of one of the arsphenamines and one of the bismuth preparations, the administration of which is begun before the fifth month of pregnancy, will prevent the transmission of the

disease to the fetus in ten out of eleven cases. When treatment is delayed until after the fifth month of gestation, only a little more than half the children will be born apparently nonsyphilitic, even though the maximum amount of treatment possible is given the expectant mother in the remaining months before birth of the child.

Almost all the evidence confirms the opinion that the pregnant woman tolerates anti-syphilitic treatment well. She is a good risk for anti-syphilitic therapy. Co-operative Clinical Group findings, for instance, show that crustaceous dermatitis and icterus, both serious complications of treatment, were commoner in syphilitic women who had never been pregnant. In the pregnant group undergoing treatment, such severe reactions as aplastic anemia, purpura hemorrhagica and death were not reported.

TREATMENT OF LATENT SYPHILIS

The occurrence of the communicable lesions of syphilis after the latent stage of the disease has begun is a rare phenomenon. Likewise, communicable relapse in latency after treatment has been instituted is very rare. Theoretically, from the standpoint of infectiousness, the important problem in latency is a determination of the potential danger of the transmission of syphilis through exposure to semen or to uterovaginal secretions of syphilitic persons. Experimental data from laboratory workers in this field are contradictory. The conflicting character of the evidence, however, suggests that the transmission of syphilis in latency by this means is of relatively infrequent occurrence.

The aim of treatment in latent syphilis, therefore, is to decrease the probability of clinical progression or relapse in comparison with the results attained when no treatment is given, and to increase the probability of cure or arrest. Out of a total of 1936 patients under treatment for latent syphilis, studied by the Co-operative Clinical Group, there were only 94 who experienced some form of relapse. Sixteen of the 94 patients had had syphilis for less than four years and sustained a communicable relapse. Thirty-one had complications involving the heart and great blood vessels, and 30 had a central-nervous-system relapse. In 5 there was visceral involvement, usually of the liver.

Of the 94 patients who had a clinical relapse, a satisfactory result was ultimately attained in 20 by the administration of treatment. In only 8 of the 30 relapsed cases with central-nervous-system involvement was enough damage done to cause distressing manifestations. In only 7 of the 31 patients with a cardiovascular relapse did the condition develop into an incapacitating one.

Clinical relapse was found to be only slightly more frequent in patients with persistently positive blood reactions than in patients whose reactions became negative. The latent syphilitic patient, therefore, is in no special danger because of the persistence of a positive blood reaction. In other words, serological resistance is not necessarily an unfavorable omen in latent syphilis, unless the spinal fluid is positive or a teleroentgenogram of the cardiovascular stripe shows suggestive evidence of involvement of the cardiovascular system.

The outline of treatment which has been recommended by the Co-operative Clinical Group for the patient with latent syphilis consists of twenty-four doses of neoarsphenamine in series of eight injections, alternating with courses of bismuth totaling from fifty to sixty doses. Periods of rest from treatment should be limited to the late latency of syphilis. In early latency (syphilis of less than four years' duration), the continuous alternating scheme described under early syphilis should be followed. In latent as in early syphilis, treatment should be by schedule and not by serological blood reaction.

CONCLUSIONS

The physician in private practice can make the greatest contribution in the campaign against syphilis by doing an efficiently performed serological test for syphilis routinely on all his patients, by treating all patients with early syphilis, using the continuous alternating scheme, by treating syphilis in pregnancy early and adequately and by preventing the late crippling manifestations of syphilis by treatment of patients with latent syphilis according to a proper schedule.

In rendering this medical service, full co-operation of the private physician with existing health authorities in reporting new patients, and thorough participation in health-department case finding and case-holding activities, are assumed.

RUPTURE OF THE RETROPERITONEAL DUODENUM*

Report of a Case

EDWARD J. OTTENHEIMER, M.D.,† AND RALPH L. GILMAN, M.D.‡

WILLIAMANTIC AND STORRS, CONNECTICUT

RUPTURE of the duodenum may occur as the result of a perforation of an ulcer, the penetration of a foreign body, accidental wounding incidental to some operative procedure or severe trauma to the abdomen.

Clinical experience has frequently verified the fact that relatively minor degrees of trauma are capable of causing rupture of parts of the intestinal tract other than the duodenum. While fixation of the latter just in front of the spine might appear to render it distinctly vulnerable, the protection afforded by the costal margin, the liver, the transverse colon and mesocolon and the mesenteric root minimizes the possibility of injury except by trauma of considerable magnitude.

Traumatic rupture of the duodenum, therefore, is not a common experience in surgery. Leibowitz¹ in 1930 amassed 176 cases from the literature, while Rowlands² found that out of 381 cases of ruptured intestines only 23 involved the duodenum. Other writers on this subject have estimated the incidence of duodenal rupture as varying from 2 to 11 per cent of all traumatic ruptures of the intestines.

These figures obviously refer to injuries of all portions of the duodenum. Traumatic rupture of the retroperitoneal portion is an exceedingly rare and grave condition, probably occurring in less than one third of traumatic duodenal ruptures, and in only a few isolated cases has recovery been noted. It is also interesting to point out that LeBauer and Paltman³ have recently reported a case of retroperitoneal rupture of a duodenal ulcer.

The rarity and gravity of traumatic rupture of the retroperitoneal duodenum seemed to justify reporting the following case.

CASE REPORT

A. N. (No. 15420) a 21-year-old student, was admitted to the Windham Community Memorial Hospital on February 22, 1939 complaining of pain in the right side. The family and past histories contributed nothing significant.

Slightly over 2 hours before admission the patient, while practicing diving in the college swimming pool misjudged

his distance from the end of the board. He stated that following his spring he grazed his head on the end of the diving board, which struck him in the right chest and right side of the abdomen as he went down. He was not rendered unconscious and was able to get out of the pool with some assistance. He complained at once of severe upper abdominal pain which within the next 30 minutes began to extend down the whole right side of the abdomen. About 2 hours after the injury he was seen by one of us (R. L. G.) and hospitalization was immediately advised. On the way to the hospital the patient vomited for the first time, although he had been nauseated since the onset. He stated that the pain was localized in the right abdomen, chiefly below the umbilicus, and was steady rather than cramplike. He had no pain in the back or in the shoulder. He had not voided for several hours.

Physical examination revealed a very well-developed muscular young man obviously in great pain lying in bed with the right thigh flexed. He was rather pale and a cold perspiration covered his skin. There was a small laceration of the scalp. Beginning about 5 cm. below the right nipple line was a broad band of linear abrasions extending down the right abdomen and right thigh. Liver dullness was present. There were moderate tenderness and muscle spasm in the whole right abdomen much more striking in the right lower quadrant. There was slight tenderness in the left lower abdomen without muscle spasm. There was no suggestion of any boardlike rigidity. Priapism was present. There were no tender areas over the spine, and the rest of the examination was essentially negative.

The blood pressure was 144/94, the temperature 97.2 F., the pulse 70 and the respirations 22. The white-cell count was 22,600 with 96 per cent polymorphonuclears, 3 per cent lymphocytes and 1 per cent transients. A catheterized specimen of the urine showed it to be grossly clear with a specific gravity of 1.031. There was a trace of albumin, but no sugar, acetone or diacetic acid was present. Microscopically there were 1 to 3 granular casts and 3 to 8 red blood cells per high-power field. Films of the lumbar spine showed no evidence of fracture or dislocation. The lateral films showed considerable air in the retroperitoneal tissues surrounding the kidneys and along the iliopsoas muscle. The preoperative diagnosis was possible ruptured viscus.

Under cyclopropane anesthesia the abdomen was opened through a low right-rectus muscle-splitting incision and the peritoneal cavity was opened without incident. There was a very small amount of clear fluid in the abdomen but in the cul-de-sac was a small amount of slightly blood-tinged fluid. The rest of the peritoneal cavity seemed to be perfectly dry and there was no evidence of any intra-abdominal hemorrhage or of the presence of intestinal contents. Beneath the serosa of the lower ascending colon and cecum and terminal ileum there were areas of white frothy fluid which crepitated on palpation. There was also crepitation in the mesentery of the terminal ileum. Just lateral to the cecum and ascending colon there was extensive retroperitoneal emphysema and this seemed to extend all the way up

*Read by title at the annual meeting of the New England Surgical Society, Storrs, Connecticut, September 29-30, 1939.

†Chief surgeon, Windham Community Memorial Hospital, Williamantic, Connecticut.

‡University physician, University of Connecticut, Storrs, Connecticut; chief of medical service, Windham Community Memorial Hospital, Williamantic, Connecticut.

on the lateral side of the ascending colon. The appendix was normal. There was no evidence of a Meckel's diverticulum. There were a few lymph nodes in the mesentery of the terminal ileum, which were not injected. The small bowel was examined and found to contain no evidence of perforation or any mesenteric hemorrhage. The liver and gall bladder were normal to palpation. No fluid or blood seemed to be coming from the upper abdomen. The right kidney was normal to palpation. The bladder was examined with the patient in the Trendelenburg position, and there was no evidence of any intraperitoneal rupture.

An incision was made into the peritoneum just lateral to the cecum, opening up the retroperitoneal space. Bubbles of gas escaped, as well as a thin, white, frothy fluid. There was no odor to this fluid. There was no evidence of any rupture of the ascending colon posteriorly. The incision in the posterior peritoneum was closed. No apparent intra-abdominal cause could be found for this retroperitoneal emphysema. It was thought that a chest injury might be responsible for this extravasation of air in the retroperitoneal space. The abdomen was therefore closed in layers in the usual manner without drainage.

Following operation the patient continued to complain of severe abdominal pain, vomited coffee-grounds material and developed a weak, thready pulse. Transfusion improved his condition temporarily, but death occurred about 38 hours postoperatively.

Autopsy At postmortem examination there was a considerable amount of blood tinged fluid in the peritoneal cavity but no evidence of peritonitis. The retroperitoneal space, especially in the right abdomen, was ballooned with a massive collection of greenish fluid. When this space was opened the fluid was found to be obviously duodenal contents, and was discovered to have come from a perforation the size of the index finger, just below the junction of the horizontal with the descending portion of the retroperitoneal duodenum. The anatomical diagnosis was rupture of the retroperitoneal duodenum, with retroperitoneal cellulitis.

It is apparent from a review of the literature that the exceedingly high mortality accompanying traumatic rupture of the duodenum is due essentially to three factors: failure to make a diagnosis sufficiently early to render proper treatment effective, failure to recognize the condition at operation, and technical difficulties encountered in repairing the retroperitoneal duodenum and establishing adequate drainage of the retroperitoneal space.

Early diagnosis is rendered extremely difficult by the fact that extravasation of duodenal contents retroperitoneally does not cause peritonitis, at least until an advanced stage has been reached and leakage has occurred into the peritoneal cavity. As a result, the dramatic boardlike rigidity of intraperitoneal duodenal rupture may not be present. The abdomen may show comparatively little muscle spasm, although tenderness of varying degree, especially in the right abdomen, is always present. Knaggs⁴ believes that a valuable diagnostic sign is a right-sided dullness, continuous with liver dullness and not shifting. He

attributes this dullness to an effusion in the retroperitoneal space on the right side, but admits that when it has developed the patient has probably reached a late and hopeless stage. The abdominal examination frequently seems to be out of proportion to the degree of the trauma, the severity of the pain and the obvious seriousness of the patient's condition. Several cases are reported, however, in which the symptomatology was so mild following the injury that the patient did not even consult a physician for several hours. Early vomiting is nearly always present.

The pain as a rule is severe and uninterrupted, and is usually greatest in the right abdomen, especially in the right lower quadrant and often in the right kidney region posteriorly. Butler and Carlson⁵ report a case in which the patient had severe pain in the testicles, which they attributed to an irritation by duodenal contents of the sympathetic chain accompanying the spermatic arteries. A similar cause cannot be ascribed to the priapism which occurred in this case, since stimulation of the sympathetic fibers tends to cause erections to disappear. Langworthy⁶ suggests three possible explanations for the priapism in this case: local trauma, including irritation of the parasympathetic fibers, traumatic obstruction to the return of venous blood from the penis, and concussion of the spinal cord without fracture of the vertebrae.

Emphysema of the lateral abdominal wall has been noted, and in 1 case, emphysema of the retroperitoneal pelvis was discovered on rectal examination. The presence of gas in the retroperitoneal space should be the most valuable early diagnostic sign, because it can be readily demonstrated by x-ray. Sperling and Rigler⁷ have reported the only other case of rupture of the retroperitoneal duodenum in which radiographic examination of the abdomen showed the presence of gas in the retroperitoneal space. These authors point out that gas in the retroperitoneal space can have only three origins: from artificial introduction, from the presence of a gas-forming bacillus in the retroperitoneal space, or from rupture of a hollow viscus having a retroperitoneal course. The latter must obviously be either the duodenum or certain portions of the large bowel. Since the first two causes can easily be eliminated, the significant value of scout films following abdominal trauma becomes at once apparent.

Failure to recognize the condition at operation has been recorded in many cases, and has occurred chiefly when exploration has been done within a short time of the injury. The peritoneal cavity may be entirely negative at this time, but various authors have reported evidences of it

or blood behind the peritoneum, and in some cases either bloody or bile-stained fluid intraperitoneally. Signs of hemorrhage have been noted in the region of the hepatic flexure, as well as yellowish gray patches subperitoneally near the duodenojejunal flexure. Fat necrosis has been observed, probably caused by the escape of pancreatic juice from the duodenum or from an associated injury to the pancreas.

Retroperitoneal emphysema has been found in many cases, and in our case was practically the only finding at operation. Since operation was performed within three hours of the injury, it is reasonable to assume that it may constitute one of the earliest evidences of rupture of the retroperitoneal duodenum. The emphysema may be so widespread as to extend beneath the serosa of the ascending colon, the cecum and the terminal ileum and into the mesentery of the terminal ileum. Butler and Carlsson⁵ noted emphysema between the transversalis fascia and peritoneum on opening the abdomen.

Cases which have been recognized at operation have presented technical difficulties of exposure, repair of the duodenal injury and adequate drainage. The symptoms and signs so often seem localized in the right lower quadrant that a low rectus incision is frequently made and is obviously inadequate. Mobilization of the upper ascending colon is usually necessary in order to gain sufficient exposure. Small ruptures have been easily repaired, but in many cases the tear has been so complete that practically an end-to-end anastomosis has had to be done. In extensive tears, the complete closing of each end, followed by gastroenterostomy, has been suggested.

Regardless of the method employed to repair the rupture, the problem of drainage of the retroperitoneal space remains. Since the cause of death in these cases is undoubtedly a retroperitoneal cellulitis, adequate drainage is of paramount importance. Knaggs,⁴ who has written an excellent paper on this injury, believes drainage anteriorly is useless, although Pedisic⁸ reports recovery of a case drained from the front and complicated postoperatively by the formation of a pancreatic pseudocyst. Many cases have been drained through the

loin. Knaggs believes that an attempt should be made to deal with it on lines similar to those adopted in extravasation of urine. He states:

The retroperitoneal space might be opened up widely by an incision carried through the parietes like that known as Morris' incision for exploration of the kidney, and this opening might be enlarged by other incisions carried backwards and forwards at right angles to the main incision at such points as would lead to the most effectual exposure of the infiltrated area. The wound would have to be kept widely open by the use of large drainage tubes and light gauze packing. No doubt such a procedure is a serious one to adopt at the close of a difficult abdominal operation, but as a fatal issue is certain unless the cellulitis can be quickly relieved its gravity should not prevent its adoption.

CONCLUSIONS

Traumatic rupture of the retroperitoneal duodenum is one of the most serious abdominal injuries.

The extraordinarily high mortality accompanying it is due largely to the lack of familiarity with its clinical picture, the failure to appreciate the significance of retroperitoneal emphysema or bile-stained fluid, the technical difficulties encountered in repairing faultlessly the duodenal rupture, and the extreme difficulty in securing efficacious drainage of the retroperitoneal space.

The discovery of gas in the retroperitoneal space, either preoperatively or at operation, is almost pathognomonic of the condition.

Radiographic examination can demonstrate the presence of gas in the retroperitoneal space, and scout films of the abdomen should therefore be a routine procedure in all cases where a ruptured viscus is suspected.

FACTORS INFLUENCING PERSISTENT AND RECURRENT HYPERTHYROIDISM*

DAVID D BERLIN, M.D.,† AND SAMUEL L GARGILL, M.D.‡

BOSTON

THE problem of persistent and recurrent thyrotoxicosis following apparently adequate subtotal thyroidectomy has been discussed perennially ever since the surgical treatment of toxic goiter was standardized on a sound basis. The striking beneficial effect of surgical treatment in the great majority of cases is widely acknowledged. In some cases, however, thyroidectomy is followed either by residual thyrotoxicosis or by recurrence of the whole syndrome, several months or years later. There is considerable difference of opinion as to the incidence of these unsatisfactory results, the incidence given in the literature vary-

Graves syndrome. Others, like Lahey and Clute,¹ Thompson et al.² and Cattell and Morgan³ conceive the solution of the problem to lie in adequate thyroidectomy, while recognizing the important factors arising from the patient as a whole. Scott⁷ even advocates total thyroidectomy as the most rational solution of the problem, believing apparently that the artificial myxedema thus produced is more easily controllable than is persistent or recurrent thyrotoxicosis.

In the last seven years, at the Endocrine Clinic of the Beth Israel Hospital, we have seen and followed carefully 15 cases of persistent or recur-

ing between 0.25 and 25 per cent, according to Thompson, Morris and Thompson.¹

Attempts to solve this problem likewise have varied considerably. Some, like Clarke and Black² and Moschocowitz,³ impressed with the fact that toxic goiter is a constitutional disease of unknown etiology, have advocated treatment of the unique personality of the patient by various means in order to control or prevent persistence and recurrence of symptoms. Crile,⁴ who perceives a biological relation between recurrent thyrotoxicosis, neurocirculatory asthenia and peptic ulcer, has advocated his dekineticizing operation or bilateral denervation of the suprarenal glands for the

recurrent thyrotoxicosis. It may be interesting and instructive to review our experience at this time and to evaluate our own approach to this problem.

MATERIAL OF STUDY

The material of this study consists of 235 unselected cases of toxic goiter operated on during the period 1932-1938. For the purposes of discussion 6 cases with recurrent thyrotoxicosis following subtotal thyroidectomy done elsewhere are listed in Table 1, 4 of these patients were treated by secondary thyroidectomy and 2 by nonsurgical means, and the former are included in our series. Most of these patients were seen in the clinic at monthly intervals for six months following thyroidectomy, and quarterly for at least a year thereafter. At each visit evidence of persistence or recurrence of symptoms and signs was carefully searched for.

*From the Endocrine Clinic, Beth Israel Hospital, Boston; the Department of Surgery, Tufts College Medical School; and the Department of Medicine, Harvard Medical School. Read in part at the annual meeting of the American Association for the Study of Goiter held in Cincinnati May 22-24, 1939.

†Professor of clinical surgery, Tufts College Medical School; first assistant visiting surgeon, Beth Israel Hospital, Boston.

‡Associate in medicine, Harvard Medical School; visiting physician, Beth Israel Hospital, Boston.

In the entire group of recurrent or persistent thyrotoxicosis there are 12 women and 3 men. It is of interest that all the men showed persistent thyrotoxicosis. Of the 5 women who were subjected to secondary thyroidectomy for either recurrence or persistence, 4 continued to show persistent thyrotoxicosis.

All these patients were closely followed. They were seen at monthly intervals, at which time a complete clinical examination, as well as determinations of the basal metabolic rate and the concentration of cholesterol in the blood, was made. As a group these patients showed no significant difference in age, sex or preoperative duration of thyrotoxicosis as compared with the rest of the patients who showed neither persistence nor recurrence following subtotal thyroidectomy. The average initial basal metabolic rate as well as the response to iodine was quite similar in the two groups. The average initial basal metabolic rate for the group with recurrence and persistence was +42 per cent, while the average basal metabolic rate at the time of persistence or recurrence was +27 per cent. The blood cholesterol values bore no constant relation to the level of the basal metabolic rate. In general they tended to fall within the limits of normal in the group with persistence and recurrence.

The group showing persistence or recurrence did differ importantly from the larger group in that it showed more pronounced vasomotor imbalance and emotional instability and a greater incidence of severe upper respiratory tract infections.

following subtotal thyroidectomy done elsewhere, it was possible to obtain sufficient reliable data as to the severity of the initial disease and the type of operation done. It will be seen from Table 1 that all these patients had had the standard bilateral subtotal thyroidectomy done four to ten years before coming to us with typical symptoms and signs of recurrence. All stated that they had been perfectly well during the intervening years, so that it is reasonably certain that they represent genuine cases of recurrent rather than persistent thyrotoxicosis. Five of these patients showed marked regrowth of the entire thyroid gland. In 1 patient no thyroid tissue could be palpated.

Three patients blamed the recurrence of the whole syndrome on certain events that had transpired shortly before the onset of symptoms. One had had a difficult menopause preceding the recurrence. Another had had frequent severe upper respiratory-tract infections as well as many financial and marital difficulties. The third had gone through a pregnancy complicated by toxemia before noting the symptoms and signs of recurrent hyperthyroidism.

The remaining 3 patients could not trace their symptoms to any particular event. It is noteworthy that in all of these there was marked regrowth of thyroid tissue.

If we now examine those cases of recurrent thyrotoxicosis that followed subtotal thyroidectomy done at our own hospital, we find much the same factors probably responsible for the recurrence of

TABLE 2. Data in Patients with Recurrent Thyrotoxicosis Following Primary Operations Done at the Beth Israel Hospital

| CASE NO. | SEX AND AGE | PRIMARY OPERATION | RECURRENCE | PROBABLE FACTORS IN RECURRENCE |
|----------|-------------|---|--|---|
| 7 | F 26 | July, 1932; bilateral subtotal thyroidectomy | February, 1933, no palpable thyroid tissue controlled with iodine and x-ray (2400 r) | Adequate thyroidectomy (?) psychic trauma |
| 8 | F 29 | August, 1932; bilateral subtotal thyroidectomy | November, 1934, no palpable thyroid tissue controlled by iodine | Recurrence following attack of acute rheumatoid arthritis |
| 9 | F 40 | April, 1933, bilateral subtotal thyroidectomy | June, 1934, regrowth of the old tissue controlled by x-ray (2100 r) and iodine | Inadequate thyroidectomy unpleasant bone situation |
| 10 | F 40 | September, 1936; right hemithyroidectomy; April, 1937, left hemithyroidectomy | May, 1938, no palpable thyroid tissue controlled by iodine | Worry over financial insecurity (?) |
| 11 | F 20 | August, 1937, bilateral subtotal thyroidectomy | April, 1938, no palpable thyroid tissue controlled by iodine | Adequate thyroidectomy (?) marked neurocirculatory stasis |

In all but Case 14 the persistent or recurrent thyrotoxicosis, as judged by the clinical state of the patient and the level of the basal metabolic rate, was definitely less severe than that existing before thyroidectomy.

FACTORS RESPONSIBLE FOR RECURRENT THYROTOXICOSIS

In all the 6 patients with recurrent thyrotoxicosis

signs and symptoms (Table 2). In only 1 of these patients was there palpable thyroid tissue associated with the recurrence. The interval elapsing between the subtotal thyroidectomy and the onset of recurrence was much shorter in this group of 5 patients, the longest being twenty-six months and the shortest eight months. In one patient a history of marked psychic trauma preceded the recurrence, in another it appeared after a severe siege

of acute rheumatoid arthritis, an unpleasant home situation figured as a probable factor in the third patient, constant worry over financial insecurity seemed to precipitate the syndrome in the fourth patient, and in the fifth there was marked vasomotor instability and all the stigmas of neurocirculatory asthenia

In Case 9 there was unquestionably inadequate subtotal thyroidectomy because of much bleeding at operation and generally poor behavior of the patient while on the operating table. The fact that she remained free from any symptoms of thyrotoxicosis for over a year was very surprising, as it was expected that she would show persistence of symptoms and signs. In Cases 7 and 11, the patients had questionably adequate thyroidectomy, despite the fact that no palpable thyroid tissue was present in the neck. In the remaining 2 patients of this group, recurrence took place in spite of apparently satisfactory thyroidectomy.

In recurrent thyrotoxicosis inadequate thyroidectomy seems to play less of a role than do factors such as psychic trauma, infections, pregnancy, the menopause and the personality of the patient.

FACORS RESPONSIBLE FOR PERSISTENT THYROTOXICOSIS

Three of our 7 patients with persistent thyrotoxicosis showed persistence of signs and symptoms two to six months following inadequate secondary subtotal thyroidectomy (Table 3). In 2 of

the thyroidectomy was most probably inadequate, since marked regeneration of the thyroid tissue occurred four months after the operation. In Case 12 the thyroidectomy was done at a time when our clinic was young and the operators less experienced in thyroid surgery, and so the persistence may probably be justifiably attributed to inadequate thyroidectomy. In Case 14, that of a very tall adolescent with only moderately severe thyrotoxicosis and slight thyroid enlargement, thyroidectomy was purposely not radical. His great height, large hands and feet, and facial features, aside from the exophthalmos, suggested hyperpituitarism with secondary thyrotoxicosis. The persistent thyrotoxicosis in him was of greater severity than that before the thyroidectomy. In Case 13, on the other hand, the patient had a radical subtotal thyroidectomy. The only factor apparently responsible for persistence in this case was the striking incidence of severe upper-respiratory-tract infections.

In persistent thyrotoxicosis inadequate thyroidectomy appears to be the chief responsible factor. This is in accord with the experience of Thompson, Morris and Thompson,¹ Cattell and Morgan² and others.

TREATMENT OF RECURRENT THYROTOXICOSIS

Four of the patients with recurrent thyrotoxicosis following subtotal thyroidectomy done elsewhere were subjected to secondary operations on the thyroid gland. In 2 of these patients a bi-

these the operation could not be completed because of injury to the right recurrent laryngeal nerve. In the third, thyroidectomy was incomplete because the remnants were almost inextricably buried in extensive and dense adhesions.

Four patients showed persistent thyrotoxicosis one to four months following bilateral subtotal thyroidectomy done at our hospital. In Case 15

lateral subtotal resection was done without any difficulty, except for a temporary right recurrent laryngeal nerve palsy in 1. In the other, regrowth of thyroid tissue and a return of symptoms and signs of hyperthyroidism occurred within four months after the apparently adequate secondary subtotal thyroidectomy. In the remaining 2 patients only subtotal hemithyroidectomy could be

done because of injury to the recurrent laryngeal nerve.

Two patients in this group (Table 1) and the 5 patients with recurrent thyrotoxicosis following subtotal thyroidectomy done at our hospital (Table 2) were treated by means other than surgical. Five patients have been treated by prolonged use of iodine alone, and 2 received x-ray therapy over short periods of time in addition to the iodine medication. The results of this type of treatment have been quite satisfactory and are in accord with the experience of others, notably Thompson, Morris and Thompson,¹ Jackson² and Haines.¹⁰ Thus Cases 1, 7 and 8 showed complete arrest of the syndrome after taking iodine for a period of one to two years. In Case 7, the patient had a normal pregnancy in 1936 without any further recurrence of symptoms or signs of thyrotoxicosis. In July, 1939, however, she returned with signs and symptoms of recurrence, which again were controlled by iodine. A secondary thyroidectomy may become necessary in her case because of fairly marked regrowth of thyroid tissue. The symptoms in Case 5 are completely controlled by iodine medication, taken regularly since April, 1935, in spite of definite regrowth of thyroid remnants. She should probably be subjected to a secondary thyroidectomy because of this but has refused surgery. Cases 9, 10 and 11 have been completely controlled by this nonsurgical regimen, but still show evidence of thyrotoxicosis when the iodine medication is omitted.

The difficulties of secondary thyroidectomy are widely appreciated. For this reason, we attempt to treat cases with recurrence either by the prolonged use of iodine alone or by iodine and one or two courses of x-ray therapy, except for those patients in whom the return of symptoms is accompanied by a definite regeneration of thyroid remnants. We resort to secondary thyroidectomy when these conservative measures fail to control the patient's symptoms completely.

TREATMENT OF PERSISTENT THYROTOXICOSIS

Medical Considerations

Six of the 7 patients with persistent thyrotoxicosis have been treated by nonsurgical means (Table 3). One patient (Case 15) showed striking regeneration of thyroid tissue within four months of an apparently adequate subtotal thyroidectomy, and she was subjected to a secondary thyroidectomy. Because of a severe reaction during the course of the operation only a right subtotal thyroidectomy was performed, with the result that symptoms and signs of thyrotoxicosis still persist, although in a much milder degree they are readily controlled by iodine medication.

Two of the patients had to be given x-ray

therapy in addition to the iodine medication. The others are completely controlled by iodine alone. One of these patients (Case 12) has taken iodine regularly since February, 1932. He has worked full time during this entire period. He still has thyrotoxicosis however, as symptoms and signs return promptly after iodine is omitted.

Thus, in our comparatively small experience, as in the larger experience of others,^{9, 10} the prolonged use of iodine has been effective in controlling the symptoms and signs of recurrent thyrotoxicosis. We give it a fair trial in all cases, except those in which there is marked regeneration of thyroid tissue. X-ray therapy may have to be added occasionally, although the effects of x-ray therapy alone have been less striking than those of iodine medication.

In general, we are in complete accord with Pemberton⁸ in regard to a certain number of patients with persistent thyrotoxicosis following apparently adequate subtotal thyroidectomy. They tend to show persistence or recurrence regardless of presumably adequate surgery. In these unfortunate individuals it seems more rational to use nonsurgical methods of treatment than to resort to total thyroidectomy as advocated by Scott.⁷ The burden of chronic persistent thyrotoxicosis may be more onerous in some patients than that of postoperative myxedema which, we agree with Scott, is quite readily and easily controlled. The difficulty lies in the selection of those patients who show persistence following subtotal thyroidectomy from the general run of patients who respond so brilliantly to that operation. It seems illogical, therefore, to subject all patients with thyrotoxicosis at the primary operation to total thyroidectomy.

Surgical Considerations

A fairly extensive experience with total thyroidectomy has taught us that radical extirpation of the gland, carefully performed, can be accomplished without the fear of tetany or a prohibitive incidence of nerve damage. In this series of patients, the majority of whom were submitted to radical subtotal resections, we had three permanent unilateral nerve injuries (1.3 per cent) and four temporary palsies with full restoration of function occurring in from a few days to eight months. In the five operations for recurrent hyperthyroidism there were two temporary nerve injuries and one permanent. We encountered no case of tetany or of mild parathyroid insufficiency. No special effort is made to search for the parathyroid glands. If one is inadvertently removed, it is promptly reimplanted in the sternomastoid muscle. It has been stated¹¹ that symptoms of hypo-

parathyroidism can probably be attributed more often to injury than to removal of the parathyroid glands. A too diligent search for them during operation should therefore be avoided. Such unnecessary operative insult is prone to result in injury to the nerve and blood supply of these glandules, with the subsequent development of symptoms, usually mild, of impaired parathyroid function.

Our experience with the primary operations for thyrotoxicosis leads us to believe that, except in cases of juvenile hyperthyroidism, radical rather than conservative resection of the gland is indicated. One might theorize that patients with long-standing severe hyperthyroidism who show a good involutonal response to iodine may well be in the terminal phase of the natural course of the disease, and should therefore be submitted to a conservative resection. Conversely it might be argued that patients with a comparatively short history are probably in the early phase of their disease, and should therefore be treated more radically. It would also seem that radical surgery is advisable in those patients who exhibit poor involution and are iodine-resistant. We have, however, with few exceptions, performed radical subtotal thyroidectomy in this series without special regard to the aforementioned considerations and an analysis of our results discloses 5 patients (21 per cent) with recurrent thyrotoxicosis and 7 (30 per cent) exhibiting residual or persistent thyrotoxic symptoms. There were 9 cases (3.9 per cent) of postoperative myxedema, in all of which the symptoms are satisfactorily controlled by small daily rations of thyroid. In most of our patients there was a temporary state of postoperative hypothyroidism with a gradual return to a normal metabolic level.

Some surgeons may be influenced toward a more conservative resection of the gland in toxic goiter in order that a liberal residue of thyroid tissue might be left for the protection of the recurrent laryngeal nerves and the parathyroid glands. While the preservation of both these structures is of course most essential, it is nevertheless true that only small remnants of either lobe of the thyroid gland may be left without seriously increasing the hazard of nerve injury or tetany, provided one is sufficiently acquainted with the normal anatomy and its variations. The application of this more radical approach would in some cases eliminate the subsequent development of persistent or recurrent hyperthyroidism.

The possibility of high superior poles sometimes projecting into the retrolaryngeal plane, retrotracheal extension of either lobe and a pyramidal lobe must all be borne in mind. They should be carefully sought for, adequately exposed

and dealt with accordingly. No tissue is left at the upper poles and the pyramidal lobe as well as the isthmus is always entirely excised in dealing with thyrotoxic patients. By completely mobilizing the lobe the amount of thyroid tissue to be left in the tracheoesophageal sulcus can then be estimated with a fair degree of accuracy. All excised tissue at the completion of the operation is routinely weighed and the probable amount of tissue left in the sulcus is estimated in grams. This more detailed method of appraising the weight of the remaining thyroid tissue has seemed to be more reliable than the previous method of reporting the operation as a "three-fourths" or "five-sixths" subtotal thyroidectomy. It is the amount of tissue left rather than the quantity removed that is the important consideration. In the average case of diffuse toxic goiter operated on, approximately 3 or 4 gm of thyroid tissue is left in each sulcus.

In secondary operations for recurrent toxic goiter the exposed remnants should be radically excised. We are coming to the belief that total or near-total excision of such remnants is probably advisable, fully realizing the technical difficulties that may be encountered. A higher incidence of hypothyroidism or myxedema will follow such maximal extirpation of all demonstrable thyroid tissue, but the untoward symptoms of a depressed metabolism are to be feared less than secondary surgery.

The recurrent nerves are frequently exposed during primary operations, but their identification has not been adopted by us as a routine in all cases. The likelihood of injury to these vital structures, however, would be considerably reduced if they were identified, whenever technically feasible, in patients operated on for recurrent Graves's disease. We have sometimes resorted to direct laryngoscopic visualization of the vocal cords after completing one side of the operation when doubt existed as to the integrity of the nerve. This part of the operative procedure is assigned to the laryngologist. If injury of the homolateral cord is disclosed, the operation is terminated and the contralateral side is completed at a later date if the nerve injury is temporary. While direct laryngoscopy may prove to be an additional burden to an already toxic patient, it is nevertheless worthy of serious consideration if its object is to prevent the tragic complication of bilateral paralysis.

DISCUSSION

The factors influencing persistent and recurrent hyperthyroidism have been studied in a series of 235 cases of toxic goiter operated on from 1932 to 1938. The incidence of persistence and recur-

rence was 51 per cent. This is strikingly low when compared with an incidence of 19.5 per cent in a similar series of 190 cases reported by Thompson, Morris and Thompson,¹ in 1930.

One of the reasons for this low incidence is that radical subtotal thyroidectomy has been done in most of the cases. Another may be that the majority of cases have not been followed for a sufficiently long period of time. It is certainly possible that more of these cases will show recurrence at some later date.

The factors probably responsible for persistence and recurrence have been found in this series to consist of inadequate thyroidectomy, the unique personality and fundamental imbalance of the patients with Graves's disease, frequent upper respiratory-tract infections, and psychic trauma from marital infelicity, financial insecurity and so forth.

No case of either persistent or recurrent thyrotoxicosis has been observed following subtotal thyroidectomy for toxic nodular goiter.

Neither the age, sex, the initial basal metabolic rate nor the degree of response to iodine appeared to play any role in persistent and recurrent thyrotoxicosis.

The symptoms and signs of many patients with persistent or recurrent thyrotoxicosis can be controlled fairly completely by iodine medication either alone or in combination with x-ray treatment.

Nevertheless, the ideal treatment for recurrent and persistent thyrotoxicosis, especially when there is marked regeneration of thyroid tissue, should consist of maximal or total excision of the thyroid remnants. Such a procedure is likely to result in postoperative myxedema, but this can be satisfactorily controlled by thyroid medication.

The incidence of permanent postoperative myxedema in this series of 235 cases was only 3.9 per cent, in spite of the fact that most of them had radical subtotal thyroidectomies.

SUMMARY

In a series of 235 cases of toxic goiter operated on between 1932 and 1938, the incidence of per-

sistent thyrotoxicosis was 3.0 per cent, and that of recurrent thyrotoxicosis 2.1 per cent.

The incidence of permanent postoperative myxedema was 3.9 per cent.

The factors responsible for most cases of persistent and recurrent thyrotoxicosis consisted of inadequate thyroidectomy, the Graves's personality with its fundamental instability frequent upper respiratory-tract infections, and psychic trauma, such as that accompanying pregnancy the menopause and financial insecurity.

A small group of patients showed persistence and recurrence without any assignable cause and in spite of apparently adequate thyroidectomy.

The symptoms and signs of many of the patients with persistent and recurrent thyrotoxicosis can be alleviated by the prolonged use of iodine medication, alone or in combination with x-ray treatment.

It is believed nevertheless, that the ideal treatment of these patients should consist of radical removal of all thyroid remnants whenever conservative methods fail to control the symptoms and in those patients showing marked regeneration of thyroid tissue.

The difficulties encountered in patients subjected to secondary thyroidectomy and ways of surmounting them are discussed.

DENTAL PROBLEMS ASSOCIATED WITH PREGNANCY*

CHARLES P. SHELDON, M.D.†

BOSTON

THERE is a tendency for obstetricians to have more interest in oral hygiene than was shown a few years ago. Authorities on obstetrics admit that oral hygiene is a good thing, that foci of infection about the mouth may have in certain cases some etiologic bearing on toxemia of pregnancy, pyelitis, puerperal infection, puerperal mastitis and recurrent abortions, and that dental surgery should be performed when it is indicated.

Perhaps the day will come when every expectant mother will be seen by a dental surgeon as a routine part of her prenatal care. This might be a procedure of some value in the prevention of obstetric complications. It certainly would contribute to the health and happiness of the mother during pregnancy. Furthermore, it would tend to ensure at the end of gestation a normal, healthy mother and baby, which, after all, is the aim of modern obstetrics.

Unfortunately, the attainment of ideals is often difficult. In spite of the adoption of prenatal care as an essential part of the obstetric program, very often nothing is done about dental problems during pregnancy unless they are real emergencies. This defect in prenatal care revolves around apathy of the laity as regards the care of their teeth, lack of appreciation by the laity of the association between dental sepsis and poor health, inadequate facilities for proper dentistry during the prenatal period, and unfounded reluctance on the part of dentists and obstetricians to recommend dental surgery during pregnancy.

Through educational measures syphilis is being taken from the category of the taboo. Most obstetricians perform routine serological tests on their patients in an attempt to eliminate congenital syphilis. Perhaps as much good would result from some plan to care adequately for dental problems during pregnancy. The medical and dental professions should co-operate in the establishment of proper facilities for dental care during pregnancy, and should educate the laity in the need for proper oral hygiene as an essential part of prenatal care.

Adequate dental care during pregnancy would aid in the elimination of foci of infection, help prevent further extension of tooth decay, promote the general health of the expectant mother and

ensure a good foundation for proper dental development in the fetus.

FOCAL INFECTIONS

The literature is replete with contradictory opinions concerning the effect of foci of infection on the development of general systemic diseases. The bulk of evidence favors the association of a septic focus with the development in certain cases of diseases such as pyelitis, bacterial endocarditis and arthritis. There is often an improvement in the medical situation with the elimination of the septic focus, be it diseased tonsils, an abscessed tooth or a chronically infected prostate or cervix.

In 1916 La Vake¹ postulated a relation between foci of infection in the teeth and tonsils and the development of toxemia of pregnancy. Talbot² in 1919 reported 97 cases of toxemia of pregnancy with a finding of dental sepsis in every case. He believed that chronic tooth sepsis threw an increased load on the excretory function of the kidney, which is already burdened by the excretory demands of advancing pregnancy. He came to the conclusion that there was a definite relation between focal infection and toxemia of pregnancy, and stated "If this relationship can be established the dental profession will hold a place in the child-conservation movement and in prophylactic medicine unequaled by any other branch of medicine."

Bland and First³ raise the possibility of puerperal infection's resulting from the transfer of infectious material from the mouth to the genital tract by the patient's hands. Glanckopf⁴ believes that foci of infection may contribute to maternal mortality, and advises dental surgery whenever it is indicated during pregnancy. Galloway⁵ found that 15 per cent of 242 women had apical abscesses during pregnancy and advised removal of these foci of infection. He and Talbot both stressed the importance of x-ray examination in the demonstration of tooth disease.

DENTAL CARIES

The connection between pregnancy and dental caries is still debatable. Mull, Bill and Kinney⁶ studied prenatal cases and, like Galloway,⁵ found that 15 per cent had dental caries. They did not believe that there was a greater development of dental caries during pregnancy and the first few weeks of lactation than would be found in a group

*Read at a meeting of the Northeastern Dental Society, Swampscott, Massachusetts, June 6, 1939.

†Assistant in obstetrics, Harvard Medical School, assistant obstetrician to outpatients, Boston Lying-in Hospital.

of nonpregnant women who were followed for the same period of time. They concluded that the average number of missing and carious teeth were proportional to the age of the individual rather than to the number of pregnancies.

Ziskin and Hotelling⁷ studied 324 pregnant women. By means of Bollecker's "caries index" they found that pregnancy does not incite dental caries. They observed that more teeth may be extracted during pregnancy than in the non-gravid state, but that the causes for extraction are not related to progress of tooth decay. They also believed that there might be some factors operating during pregnancy which actually prevented the development of dental caries.

Bland and First⁸ believe that the chief deleterious effect of pregnancy is to aggravate the dental caries already present rather than to produce caries in healthy teeth. Kerwin⁴ maintains that since the enamel has no blood vessels, calcium cannot be absorbed from the teeth into the blood stream to meet the demands of the growing fetal skeletal system. Schour, Chandler and Tweedy⁹ removed the parathyroid glands from rats. In those that survived over four months, repeated pregnancies and lactations failed to produce any histological evidence of calcium withdrawal from the calcified tissue of the teeth.

The exact cause of tooth decay is unknown. Alterations of the hydrogen ion concentration, carbohydrate fermentation, vitamin deficiency and disturbances of the calcium-phosphorus blood levels are considered possible etiologic factors. Of perhaps even greater significance is the factor of heredity, which naturally is difficult to evaluate. There is some evidence that good teeth are inherited by some family strains, while others have teeth that develop dental caries in spite of every prophylactic measure. If this is true, prenatal influences may be of some importance. It is therefore desirable for every pregnant woman to receive dietary and hygienic measures during the antepartum period, which will lay a good foundation for the proper development of tooth structures in the growing embryo. Since tooth structures are present by the end of the second gestational month and calcification is evident as early as the fourth month, therapeutic procedures should be carried out throughout the pregnancy. In fact, an ideal situation is one in which a woman undertakes a pregnancy only after a thorough dental survey has been conducted as a preconceptional measure, at which time the dental surgeon corrects all defects, so that the patient starts the pregnancy with sound teeth. It is then the problem of the obstetrician to institute the necessary dietary measures which will meet the demands of the in-

creased metabolism associated with pregnancy, and will supply the growing embryo with the foundation building materials which, if not present in adequate amounts, will be abstracted from the maternal tissues.

DIET DURING PREGNANCY

Not only must carbohydrates, proteins, fats, minerals and vitamins be present in liberal amounts in the diet of the expectant mother, but they must be assimilable. For instance, we know that even though there may be an adequate intake of calcium in the diet, rickets will develop during childhood if vitamin D is not available in sufficient amounts to promote absorption of calcium. There may be, and probably are, many other relations in metabolism similar to that of vitamin D and calcium.

Rosebury and Foley¹⁰ produced experimental evidence that pregnancy and lactation do not result in increased tooth decay, although bone calcification and the formation of new dentine is defective if the diet is deficient in calcium and vitamin D.

Agnew, Agnew and Tisdall¹¹ fed rats on diets low in phosphorus and vitamin D, this resulted in a high incidence of dental caries. The amount of calcium in the diet did not seem to influence the development of caries.

Howe¹² was able to produce decalcification of the teeth of guinea pigs by placing them on a diet deficient in anti-scorbutic factor, and to cure the process by feeding an adequate diet. He discovered that diets deficient in vitamin C resulted in a diminution of the amount of ash and calcium and an increase in the amount of magnesium in the teeth, even though the calcium in the diet was normal.¹³

Animal experimentation suggests that there is an increased demand for vitamins during pregnancy and lactation. Teel, Burke and Draper¹⁴ have shown that the fetus acts as a parasite on the mother, so that she needs appreciably greater amounts of vitamin C during pregnancy than she does during the non-gravid state. This increased maternal need for vitamin C was demonstrated to persist during lactation.¹⁵

It should be remembered that a well balanced diet built up around five main articles (meat, eggs, milk, vegetables and fruits) will supply the essential elements. One or two eggs daily will correct a deficiency of vitamin D. One quart of milk supplies 1.2 gm of calcium which is adequate for the normal demands (1 gm daily).

If the expectant mother is unable to drink milk and to eat proper amounts of green vegetables,

it becomes necessary to add calcium to the diet. During those months when there is little sunshine it is advisable to add some form of cod-liver oil, because of the beneficial effects of vitamin D in the promotion of absorption of calcium. If the diet is deficient in fruit juices, or if the patient has spongy gums which bleed easily, ascorbic acid is an essential therapeutic procedure.

As obstetricians and dentists become increasingly scientifically minded, there is a tendency to impart to the patient an impression that she is afflicted with a terrible disease, namely pregnancy. I should like to make a plea that we change our tactics and try to impress the pregnant woman with the idea that she does not have a disease but is simply experiencing a normal physiologic process. We can help to inculcate this attitude by the intelligent administration of vitamins and other necessary food articles when they seem to be deficient in the patient's diet, instead of blindly giving shotgun mixtures and supplying excessive amounts on the theory that if a little is beneficial a lot should do much more good.

The Council on Dental Therapeutics¹⁰ states that the addition of calcium and phosphorus in the presence of an adequate diet does not necessarily promote the development of sound teeth in the human fetus.

We have not yet properly evaluated the possible harmful effects of the administration of vitamins and minerals in excess of the bodily needs. Brehm¹⁷ believes that viosterol causes calcification of the placenta, which is greatly increased when there is an excess of calcium in the diet. Finola, Trump and Grimson¹⁸ demonstrated by roentgenograms increased bone density in babies born of mothers treated with dicalcium phosphate and viosterol. Let us, then, as physicians and dentists, cease to treat our patients empirically, and administer drugs only when they are needed.

ORAL HYGIENE

A clean mouth contributes to the comfort and health of the obstetric patient. Dental hygiene should be fully explained by the attending physician. The patient should be instructed to brush her teeth after each meal. The gums should be massaged with the toothbrush and the teeth should be brushed from the gums toward the biting surfaces. An alkaline mouthwash should be used after each brushing.

Dental hygiene is but one part of the general hygiene of pregnancy, and should be combined with such measures as fresh air, sunshine, exercise, rest, a clean body and a proper mental attitude on the part of the patient.

DENTAL SURGERY DURING PREGNANCY

The dental surgeon may safely perform during pregnancy any procedure which is indicated for the correction of tooth defects, but should first consult the attending obstetrician. Ordinarily it is unwise to perform dental surgery at that time of the month when the menses would occur if the patient were not pregnant, since this is the most likely time for abortion to occur. On the other hand, abortion following tooth extraction is exceedingly uncommon.

In general, dentists treat pyorrhea, fill cavities, drain abscesses, extract roots and cauterize polyps during pregnancy. The possible harmful effects of extracting teeth in order to eliminate foci of infection should be borne in mind, since this may spread the infection rather than eliminate it. Rowley,¹⁹ therefore, advises repeated examinations of the temperature, urine and leukocyte count during and following extractions in order to note reaction. He cultured the roots of devitalized teeth and consistently showed a positive growth of streptococci of either the viridans or hemolytic types.

The patient should not be subjected to prolonged exhausting operative procedures. If many teeth must be extracted it is preferable to carry this out in several stages.

Local anesthesia is preferable to inhalation anesthesia, although nitrous oxide may be used with comparative safety.

Since many obstetric patients now receive potent analgesic drugs during labor and inhalation anesthesia at delivery, it is increasingly important that there be no loose teeth or insecure fillings which can be inhaled into the air passages when the patient is under the effect of one of these drugs. Proper dental therapy will greatly diminish this danger.

SUMMARY AND CONCLUSIONS

Dentistry should be an essential part of prenatal and postnatal care.

Foci of infection about the mouth may in some cases have an etiologic bearing on the development of obstetric complications such as toxemia, pyelitis, mastitis, puerperal infection, cardiac decompensation and recurrent abortion.

A negative calcium-phosphorus balance and vitamin C and D deficiencies may have a deleterious effect on dental caries during pregnancy.

Dentists and obstetricians should prescribe calcium, viosterol, ascorbic acid and other essential elements when they seem to be lacking. There is no evidence that the administration of these substances in amounts in excess of the bodily needs

will have a beneficial effect on either the mother or the baby

Oral hygiene is an essential part of the general hygiene of pregnancy

Pregnancy is no contraindication to dental surgery. On the contrary, proper dental surgery may have a beneficial effect on the pregnancy

A CLINICAL AND LABORATORY STUDY OF THE INCIDENCE OF FUNGI IN PATIENTS WITH CUTANEOUS ERUPTIONS*

JOHN G. DOWNING M.D.,† BEULAH MERRILL B.A.,‡ and DAVID L. BELDING M.D.§

BOSTON

DURING the year from July 1, 1938, to July 1, 1939, 476 patients with cutaneous eruptions were examined at the Dermatological Clinic of the Boston City Hospital for the presence of fungi. The existence of fungous infection was definitely or remotely suspected in most of these patients. Scrapings were taken from the skin of these patients, not only at the site of the lesion but elsewhere, for example the feet. Direct microscopic examination of the scrapings from the lesions in cover glass mounts with 20 per cent potassium hydroxide and cultures on Sabouraud's medium were made. The cultural methods were the more informative, since they permitted the identification of species as well as that of genera. The value of direct microscopic examination was evidenced in cases infected with tinea versicolor, since the cultivation of the causative organism was unsatisfactory. Except in the sections of this report especially relating to cultures, the positive findings represent the results of the combined methods.

tures and 27.2 per cent by direct examination. Of the 179 cases with positive findings, both cultures and scrapings were positive in 94 (52.5 per cent), cultures were positive and scrapings negative in 47 (26.2 per cent), and cultures were negative and

| Malassezia | 11 | 100 | 0 |
| Total | 179 | | |
| A cases | | 4 | 79 |

scrapings positive in 38 (21.2 per cent). If cultures had been the only method used 141 positive results (78.7 per cent) would have been obtained and if microscopical examination only had been made, 132 (73.7 per cent) would have been found. These figures indicate the necessity of using both methods in the laboratory diagnosis of infections due to fungi.

The relative value of the two methods varied with the genus of the invading fungus as shown in Table 1. Infections by *Microsporon*, *Trichophyton*, *Epidermophyton* and *Malassezia* were

DIRECT MICROSCOPICAL EXAMINATION VERSUS CULTURES

Positive findings were obtained in 37.6 per cent of the 476 patients examined, 29.6 per cent by cul-

more readily demonstrated by direct microscopical examination than by culture. The other genera of fungi shown in Table 1 were detected chiefly by culture. *Monilia albicans* was recognized in 92 per cent of the positive cases by culture and in 65 per cent by microscopical examination. The other species of *Monilia*, which probably play no important etiologic role, were detected only by culture. Infections with *Mycoderma* and *Cryptococcus* were recognized chiefly by cultural methods.

SEASONAL INCIDENCE OF FUNGI IN DISEASES OF THE SKIN

Table 2 gives the percentage of cases in which fungi were recognized by laboratory examination.

TABLE 2 *Percentage of Positive Findings of Fungi by Months*

| MONTH | TOTAL NO OF CASES | POSITIVE CASES NO | PER CENT |
|-----------|-------------------|-------------------|----------|
| 1938 | | | |
| July | 20 | 9 | 45.0 |
| August | 48 | 28 | 48.3 |
| September | 35 | 16 | 45.7 |
| October | 41 | 18 | 43.9 |
| November | 38 | 15 | 39.5 |

| May | 53 | 14 | 26.4 |
| June | 37 | 10 | 27.0 |
| Totals | 476 | 179 | |

tion, arranged by months. Of 476 cases, 179 (37.6 per cent) showed the presence of fungi. These fungi appear to be the etiologic agents, except possibly the species of *Monilia* other than *M. albicans* and the genera *Mycoderma* and *Cryptococcus*.

The seasonal distribution of the series has little

groups of three months so as to separate the summer-vacation period.

Tinea capitis (*Microsporon* infection) occurred almost exclusively in children. During the summer months the number of patients was about half as large as that during the other months, evidently because of the vacation period. *Tinea circinata* did not show a similar decline during this

TABLE 3 *Relation of Season and Temperature to the Percentage of Positive Findings of Fungi*

| PERIOD | PERCENTAGE OF POSITIVE FINDINGS | | | | | |
|---|---------------------------------|--------------|---------------|-----------------|-----------------|---|
| | MEAN TEMPERATURE (BOTTOM) | ALL DISEASES | TINEA CAPITIS | TINEA CIRCINATA | DERMATOPHYTOSIS | EROSIO INTERDIGITALIS, ONYCHOMYCOSIS AND PARONYCHIA |
| | °F | | | | | |
| Six warm months (May to November) | 63.9 | 40.6 | 88.8 | 82.6 | 56.5 | 70.6 |
| Six cold months (November to May) | 35.8 | 34.7 | 80.7 | 60.0 | 51.4 | 66.7 |
| Four very warm months (June to October) | 68.1 | 45.0 | 100.0 | 86.7 | 55.0 | 63.3 |
| Four very cold months (December to April) | 34.1 | 34.7 | 77.3 | 58.3 | 52.4 | 58.3 |

period. *Dermatophytosis*, due in the majority of cases to *Trichophyton*, was less prevalent during the coldest months, whereas *erosio interdigitalis* and other conditions of the hands due to *Monilia* had no seasonal variation.

The percentage of positive laboratory findings tended to increase during the warm weather. A comparison of the warm and cold months in Table 3 shows that during the warm weather there was a marked increase in the percentage of positive findings in *tinea capitis* and *tinea circinata*, and slight increase in *dermatophytosis* and in *erosio interdigitalis* and other hand infections.

TABLE 4 *Clinical Diagnoses and Positive Findings of Fungi*

significance other than indicating a seasonal variation in the percentage of positive findings. More information is obtained when the prevalences of the four commonest diseases—*tinea capitis*, *tinea circinata*, *dermatophytosis* and the combined *Monilia* infections of *erosio interdigitalis*, *onychomycosis* and *paronychia*—are arranged in

THE INCIDENCE OF FUNGI IN CERTAIN SKIN DISEASES

The percentage of positive laboratory findings of fungi depends on the cutaneous eruption. Table 4 gives the percentage of positive examinations for several diseases commonly associated with fun

gous infections and the distribution of the fungi according to genera

Tinea capitis A high percentage of positive results (84 per cent) was obtained in this disease. All the fungi found were of the genus *Microsporum*. This disease is easily recognized clinically, which explains the high percentage of positive findings.

Tinea circinata Patients with this disease also yielded a fairly high percentage of positive results (71 per cent). With a single exception all the fungi were of the genus *Microsporum*.

Dermatophytosis Over half the patients (55 per cent) with dermatophytosis gave positive findings. Of the 54 fungi, 31 were of the genus *Trichophyton* and the remainder were of the genera *Monilia*, *Cryptococcus* and *Mycoderma*. Either laboratory methods were less effective in detecting fungi in this disease or the clinical diagnosis of dermatophytosis was wrong.

M. gypsum 1 and *M. lanosum* 42. The 24 positive cultures of *Trichophyton* consisted of the following species: *T. gypsum* 10, *T. purpureum* 6, and unclassified, 8. The 3 species of *Epidermophyton* were all *E. floccosum*. The 37 cultures of *Monilia* consisted of the following species: *M. albicans* 24, and unclassified, 13.

ANATOMICAL DISTRIBUTION OF FUNGI

The various cutaneous locations from which the fungi were obtained are arranged in Table 5 according to the genus of the fungus. The sources of the 179 positive findings were as follows: head, 29 per cent, body, 19 per cent, upper extremities, 26 per cent, and lower extremities, 26 per cent.

Fungi of the genus *Microsporum* were distributed thus: head, 67 per cent, body, 18 per cent, upper extremities, 12 per cent, and lower extremities, 3 per cent. Those of the genus *Trichophyton* were

TABLE 5 Anatomical Distribution of Fungi Isolated from Patients

| Genus | No. of Positive Findings | Head | | Body | | Upper Extremities | | Lower Extremities | |
|-----------------------|--------------------------|-------|------|------|------|-------------------|-------|-------------------|------|
| | | Scalp | Face | Body | Arms | Arms | Hands | Legs | Feet |
| <i>Microsporum</i> | 74 | 41 | 9 | 10 | | 3 | | 2 | |
| <i>Trichophyton</i> | 33 | | | | | 1 | | | 25 |
| <i>Epidermophyton</i> | 4 | | | | 4 | | | 3 | |
| <i>Monilia</i> | | | | | | | | | |
| <i>M. albicans</i> | 26 | | 2 | 1 | 1 | | 20 | | 2 |
| Other species | 13 | | | | | 1 | 5 | 6 | |
| <i>Cryptococcus</i> | 11 | | | | | 1 | 2 | 1 | 7 |
| <i>Mycoderma</i> | 7 | | | 11 | | | 4 | | 1 |
| <i>Malaissia</i> | 11 | | | | | | | | |
| Totals | | 41 | 11 | 23 | 5 | 6 | 34 | 12 | 35 |
| Grand totals | 179 | | | | 34 | | 46 | | 47 |

Erosio interdigitalis The interdigital lesions of the hands showed the presence of *Monilia* in 74 per cent of the cases. In 88 per cent of this group the lesions showed the presence of *M. albicans*.

Contact dermatitis The small number of fungi (3 per cent) obtained from patients with contact dermatitis—mostly old cases—indicates that secondary infection with fungi is not so frequent as one might expect from the literature. Known pathogens were detected in only 3 of 215 patients.

SPECIES OF FUNGI

Only those fungi isolated by culture were identified as to species. It was not always possible to determine accurately the exact species, owing to the lack of standard classification and to the difficulty of classifying the aberrant forms, which do not correspond exactly to established types. For this reason it has been necessary to list some of our cultures as unidentified species. No attempt was made to classify species of the genera *Cryptococcus* and *Mycoderma*.

The 60 positive cultures of *Microsporum* consisted of the following species: *M. audouinii*, 17,

obtained as follows: body, 3 per cent, upper extremities, 12 per cent, and lower extremities, chiefly feet, 85 per cent. *Monilia albicans* was found as follows: head (face), 8 per cent, body, 8 per cent, upper extremities (hands), 76 per cent, and lower extremities (feet), 8 per cent.

DISCUSSION

This type of study reveals several points worthy of comment.

A systematic examination of patients for fungi has a distinct value, since the finding of fungi, especially in the cases of contact dermatitis, may mean a great difference in prognosis and treatment. However, the finding of a pathogenic fungus in the skin of a patient showing a cutaneous eruption does not necessarily mean that the eruption is due to the fungus, since an occasional pathogen may be found on a normal skin.

Despite the fact that the routine of a large clinic necessitates the services of physicians who are only part-time dermatologists, the diagnosis of contact dermatitis as a disease distinct from fungous infection was 97 per cent correct. On the other

hand, in tinea capitis, in which the diagnosis should ordinarily be correct both clinically and culturally in 100 per cent of cases, it was impossible to demonstrate the fungi in 16 per cent of the patients, the result either of mistakes in clinical diagnosis or of faulty technic in obtaining laboratory specimens

The trend of dermatological diagnoses has changed. Today it is important to use both clinical and laboratory methods of diagnosis for diseases of the skin. With improved laboratory technic there will be fewer negative findings in mycotic infection, especially when the lesions are observed by those trained in their clinical recognition. The study of mycology in relation to cutaneous and systemic affections is of increasing value in the diagnosis, prognosis and treatment of these diseases.

SUMMARY

A statistical report is presented on the incidence of fungi in cutaneous eruptions at the Dermatological Clinic of the Boston City Hospital from July, 1938, to July, 1939.

Positive findings were obtained in 37.6 per cent of 476 patients in whom the existence of fungous infections was definitely or remotely suspected.

Two methods of laboratory diagnosis were employed: direct microscopical examination and cul-

tures. By the former method 73.7 per cent of the total positives were obtained, and by the latter 78.7 per cent. The relative value of the two methods depends on the genus of fungus concerned. Both should be used in the diagnosis of fungous infections.

The percentage of positive findings varies with the different diseases. Tinea capitis, tinea circinata and *erosio interdigitalis* give a high percentage of positives, and dermatophytosis a fair percentage. Contact dermatitis has an extremely low percentage, a finding which proves that secondary infection with fungi is more or less infrequent.

The incidence of tinea capitis, most prevalent in children, shows a seasonal variation, with a decline during the summer-vacation months. The cases of dermatophytosis decrease during the cold months.

The percentage of positive findings is highest in warm weather.

The 179 fungi comprised seven genera, of which the three commonest were *Microsporon* (41.3 per cent), *Monilia* (21.8 per cent) and *Trichophyton* (18.5 per cent).

The anatomical distribution of the lesions from which fungi were detected was as follows: head, 29 per cent, body, 19 per cent, upper extremities, 26 per cent, and lower extremities, 26 per cent.

REPORT ON MEDICAL PROGRESS

ABDOMINAL SURGERY

ARTHUR W. ALLEN, M.D.*

BOSTON

MANY outstanding contributions have been made to the field of abdominal surgery during the past year. It will not be possible to discuss them all in this review. Some of them need further confirmation to prove their practical value, and may be mentioned in a later report. Although it will be necessary to consider some of the same organs or systems that were discussed in the previous report,¹ it is believed that this is justifiable on the basis of the frequency with which some of the conditions are met, and the better understanding that has come about concerning their management. Of necessity, such a report must be incomplete.

*Lecturer in surgery, Harvard Medical School; chief of the East Surgical Service, Massachusetts General Hospital, Boston.

PERITONITIS

More and more evidence has been collected indicating that peritonitis of severe and fulminating types, when not based on a continued leak into the peritoneal cavity from a hollow viscus, should in many cases be treated by a conservative regimen. If and when localization of the infectious process takes place, the abscess should be drained as early as its existence can be reasonably assured. This is particularly true in peritonitis associated with appendicitis. Cases appearing after full-blown peritonitis has developed from appendicitis are more safely treated on a conservative basis until localization is obvious. The abscesses — if they develop — should be drained be-

fore they have progressed to a point of intra abdominal rupture, since a secondary generalized insult to the peritoneal cavity is almost invariably fatal.

Rarely should the appendix be removed during the drainage of a localized abscess, but instead, secondary appendectomy should be planned at a subsequent date. Although of necessity the exact time for the removal of the appendix under certain circumstances must be variable, there has been a considerable tendency toward delaying this procedure too long. In some cases it is best to remove the appendix before the patient is discharged from the hospital, in others, the appointment for return for this operation should be between six and eight weeks after discharge. If delay is greater than this, a recurrence of the acute process may develop, with resulting secondary abscess formation, which will preclude appendectomy at the time of the second entry.

Various methods of combating acute peritonitis have been advocated. In early cases one may consider seriously the use of Steinberg's⁷ colibac trogen. It would appear that this product marshals the immune forces within the peritoneal cavity with much greater rapidity than does Nature. The work of Coller, Ransom and Rufe⁸ seems to support the efficacy of this agent. A better use for it might be considered when there has been gross contamination of the peritoneal cavity by accident during an operation on the colon. Experimental evidence indicates that this material may be of value, and apparently it offers considerable protection to experimental animals whose peritoneal cavities are contaminated purposely by the fecal stream. One must be careful, however, not to utilize any material of this sort as a substitute for carefully planned—two-stage if necessary—clean abdominal surgery when dealing with the colon. Other agents, such as the lyophilic serum now advocated by Bower,⁹ may prove useful. He has presented some evidence that the routine use of this serum in peritonitis reduces the mortality. Confirmation of this work is needed. Sul familamide in peritonitis has naturally been tried and recommended by some observers, the results as yet are not convincing, although further developments along this line and with this agent or some kindred chemical may prove of great value.

SUBDIAPHRAGMATIC ABSCESS

Faxon⁶ has recently reviewed this subject from the records of the Massachusetts General Hospital. The results of early diagnosis and adequate drainage are very convincing. Approach through the bed of the twelfth rib has been rewarded by a great lowering of the mortality. As Ochsner and

DeBakey⁵ pointed out in their original description of this method of drainage, one must be sure that the incision through the bed of the rib is not in the oblique direction of the rib but transversely to it and opposite the first lumbar transverse process. If this precaution is observed one can not enter the pleural cavity by accident. The advantages of being able to drain a subhepatic abscess by an extension of this incision, as well as the common right posterolateral space, are to be considered, since a high percentage of all subphrenic accumulations occur in these regions. Careful x-ray examinations, supported by injections of Lipiodol where a sinus is present, make it possible to localize the abscess accurately. The trans pleural route of drainage has been attended by a much higher mortality than has the lower approach.

THE BILIARY SYSTEM

There is still considerable controversy concerning the advisability of immediate or delayed operation in acute gall bladder disease. Evidence has been offered that supports both views. Recent contributions by Glenn¹ from the New York Hospital indicate that early operation is associated with a lower mortality than is delayed surgery, on the basis that a considerable number of gangrenous gall bladders perforate. On the other hand, Behrend,² of Philadelphia, offers considerable evidence that emergency operations on the gall bladder are hazardous, and that if they are undertaken the gall bladder should be drained and not removed. He believes that generalized peritonitis following perforation of the gall bladder is very rare, and that the local inflammations which may occur following a subacute perforation can be adequately treated if a less radical attitude is adopted. From the New York Postgraduate Hospital, statistical data by Hotz³ and Carter, Heyd and Hotz¹⁰ are of interest. This material has recently been summarized by Heyd.¹¹ He points out that patients who were operated on in the first six hours after admission to the hospital had a mortality rate double that of those operated on between six and twenty-four hours after admission. This would indicate that the patients may have had the process for a great many hours or, at times, days prior to admission. Preoperative dehydration seemed to be a definite factor in the high mortality. Those patients who had their dehydration combated were in a much better condition to withstand the operative procedure than were those operated on several hours after admission. It is interesting that most of the controversy which has been carried on has been on the basis of when the operation should be done in relation to

hospital admission rather than in relation to the actual duration of the acute process. A study is now being undertaken in order to ascertain, if possible, the safety of operation in acute gall-bladder disease on the basis of the duration of symptoms rather than on that of the hours after admission.

Coller and Jackson,¹² of Ann Arbor, have contributed the results of their study on the dextrose tolerance in gall-bladder disease; they believe that some cases which have been diagnosed previously as hyperinsulinism have, as a matter of fact, been those of hypoglycemia due to liver damage. They think that the longer acute gall-bladder disease exists, the more danger there is to the liver. They believe that dextrose-tolerance curves may be very valuable in determining the safety of operation, and that the sooner the liver is relieved of the burden of the inflammatory process of the acute gall bladder, the less likelihood there is of a fatality from liver damage.

Wilson,¹³ of Toronto, has offered a new method of repair of an injured common duct. This constitutes constructing a tunnel in the anterior wall of the stomach over a tube, the proximal end of which is secured in the stump of the injured common hepatic duct. Wilson's intention was to do a second operation in order to establish drainage from his new peritonealized tube into the stomach itself, but he found that drainage took place spontaneously. I have tried this method in one case, establishing the continuity through the gastric mucosa at the time of the primary operation. It only remains to be seen whether such a tunnel will contract and become as troublesome as most of the artificial ducts that have previously been made. In another case I cut across the jejunum and anastomosed it to the stump of the common hepatic duct, re-establishing continuity in the jejunum by an end-to-side anastomosis of the Roux Y type. This may be a better operation when possible, since the peristaltic current is away from the liver rather than toward it. I obtained the idea of using this type of repair from Whipple's¹⁴ article on two-stage resection for carcinoma of the head of the pancreas or duodenum.

Every conceivable precaution should be taken to prevent injury to the common and hepatic ducts during cholecystectomy. I still believe that in any gall-bladder operation—where, owing to the disease present, to the obesity of the patient or to adhesions of the duodenum in this region it is difficult to identify accurately the right and left hepatic ducts, the common duct and the cystic duct, as well as the cystic artery—the gall bladder should not be removed from the ducts toward the fundus. A reverse procedure, using artificial

edema in the wall of the gall bladder, will result in fewer accidents to the ducts in a large percentage of operations.

Wallace and I,¹⁵ have reported follow-up studies on patients with common-duct operations at the Massachusetts General Hospital for the last nine years. We found that the most reliable information, aside from jaundice, to indicate stone in the common duct is frequency of attacks. Of 66 patients who had attacks less than one week apart, 60 had stones in the common or hepatic ducts at operation, regardless of the size or thickness of the duct. Among 2088 operations on the extrahepatic biliary system in the last nine years, 775 patients had common-duct explorations—an incidence of 37.6 per cent. In the last four years, 20.7 per cent of these patients had stones in the common duct. Patients recorded as having had mud or detritus in the ducts were not classified with those who had had stones. Of the 775 patients with common-duct exploration, 561 had the papilla of Vater instrumentated. The average dilatation was 7 mm and was carried out by the graduated metal dilators of Bakes.¹⁶ There were no accidents coincident with the passage of these bougies through the papilla, such as ascending cholangitis, duodenal reflux or fulminating infection. There has been no evidence of subsequent cicatricial constriction of the duct outlet. Four of these patients returned with symptoms and had stones removed from the ducts. Of the 214 patients who did not have instrumentation of the papilla, 9 were reoperated on for stone, and 10 others continued to have symptoms thought to be due to stone in the duct or spasm of the sphincter of Oddi.

The dramatic effects of vitamin K on the hemorrhagic tendencies in jaundiced patients have now become standardized sufficiently for one to be assured of the permanent elimination of fatal hemorrhage in such cases. A synthetic substance in the form of a naphthoquinone derivative works much more quickly than does vitamin K obtained from natural sources, so that patients may be prepared for surgery much more rapidly. One of these synthetic products can be administered parenterally, with effectiveness, according to Stewart.¹⁷ In conjunction with the new substance, studies are being made regarding the prothrombin level in patients bleeding from lesions other than those produced by jaundice. In some cases of bleeding in ulcerative colitis and hypertrophic gastritis, the prothrombin level has been found low and the patients have responded to the administration of vitamin K. This substance is almost sure to prove a specific in hemorrhagic disease of the newborn.

GASTRIC AND DUODENAL ULCER

Increasing evidence is being accumulated as a warning against the early loss of symptoms and even against improvement in the roentgenological picture in gastric ulceration, since certain malignant ulcerations improve in this manner on a conservative regimen. Patients with gastric ulceration should be closely followed at frequent intervals until the lesion is entirely healed, else a certain number of malignant ulcerations will be overlooked. One must not rely on the presence of hydrochloric acid in the stomach as a guide to the benign character of the ulceration, since many cases of carcinoma of the stomach have a normal acidity, and occasional cases a high one. If a gastric ulceration is followed by the internist and roentgenologist at intervals of ten days, a decision regarding the need of surgery can be made within a month. It is better to resect a stomach for a benign ulcer than to overlook an ulcer with malignant degeneration. Serial sections of many gastric ulcerations will show cancer in small areas. Since this is the most curable type of gastric cancer, one should not be disappointed should the pathologist fail to find malignant disease in a lesion operated on because it had failed to respond as rapidly as one thought it should with conservative measures.

In subtotal gastrectomies for duodenal ulcer, it has become evident that one should not leave the mucous lining of the antrum of the stomach in situ. The presence of many deeply penetrating ulcers with marked inflammatory reaction involving the head of the pancreas and the region of the bile ducts, makes excision of this portion of the duodenum hazardous. For this reason, the so-called gastrectomy for exclusion has been popularized. When Finsterer¹⁸ first advocated this method of avoiding the extra risk of resecting a portion of the duodenum involved in a large inflammatory mass, he believed that if the antrum was left the mucosa should be removed from it. Other investigators have held the same opinion although, as time has passed, neglect to attend to this detail has caused a great many catastrophes. The mucosa of the antrum apparently contains an acid activating substance which stimulates an excess of acidity from any acid cells remaining in the unresected proximal portion of the stomach. Jejunal ulcers have been prone to follow this type of operation (gastrectomy for exclusion) when the entire antrum has been left behind. Ogilvie¹⁹ calls attention to this fact, and reports a very large percentage of jejunal ulcers in a small series of exclusion procedures. Graham²⁰ has had a similar experience. I have fallen into the same error, much to my regret, and have had to reoperate on

a few patients and remove the remaining antrum in order to produce permanent alkalinity in the proximal segment of the stomach. Incidentally, the removal of the mucous lining of the antrum makes the closure of the serous and muscular coats of this structure very much easier. It is possible that there may be an influence on acidity in addition to that coming from the mucosa of the segment. It is hoped that a series of experiments soon to be carried out at the Massachusetts General Hospital by Dr. Oliver Cope will prove this point one way or the other. So far, no patients who have had gastrectomy for exclusion plus the removal of the mucous membrane from the remaining antrum have developed jejunal ulcer.

I am impressed with the difficulty of performing gastric surgery on fat patients—not that the obesity interferes with the technical procedure but that the traumatized fatty mesocolon through which a posterior anastomosis is made is apt to produce a malfunctioning stoma. This is particularly true in secondary operations for a jejunal ulcer, since all these patients have been fed on such a high fat diet that they have large deposits of adipose tissue in their mesenteries. A large fat omentum makes it more difficult to perform an anterior anastomosis, since the mesentery of the jejunum is not long enough to go around the omentum and colon without tension. As the least objectionable method, I have on occasion divided the omentum from its border to the colon and brought the jejunum through this rent, with satisfactory results. In fat patients who have an obstructive lesion of a benign character at the pylorus, one should seriously consider pyloroplasty or gastroduodenostomy rather than a posterior gastroenterostomy. Walters²¹ has also recognized that obese patients with stomach lesions require special attention as regards the type of anastomosis done, and refers to 11 selected obese patients on whom he has operated.

Malfunctioning stomas are still a burden to any surgeon who attempts gastric surgery. Hoag,²² of San Francisco, advocates an operation which he calls jejuno-plasty. This necessitates exposing the original anastomosis sufficiently well to do a plastic procedure on the two limbs of the jejunum. This is done, much as in the Finney pyloroplasty, by using the two limbs of the jejunum instead of the duodenum and antrum of the stomach. Hoag reports several cases with good results, and believes that this procedure is more logical than any other yet devised. It may not have the hazard of stomal ulcer so common after enteroenterostomy, since the alkaline juices are not diverted from the line of anastomosis. Abbott and Rawson²³ describe a two-way tube to be used

in all anastomoses between the stomach and intestine. It has two compartments, one of which is supposed to drain the stomach contents to the outside by siphonage or suction, while the second passes on for quite a distance to the distal limb of the jejunum. This method has the advantage of enabling one to feed the patient through the long tube at an earlier date than one might without some such provision. The small holes in the portion of the tube that remains in the stomach are not entirely adequate to keep the stomach decompressed, and vomiting may take place in spite of the tube. It is possible that a larger tube with larger openings might obviate this disadvantage. Abbott and Rawson's tube may be particularly helpful from the standpoint of early feeding, but one very much questions whether it will solve the problem of some of the more serious grades of malfunctioning stoma. The average malfunctioning stoma will right itself in a period of seven to ten days if the serum protein can be maintained at a high level. The blood chemical findings must be carefully followed, and if there is no sign of material passing into the distal limb of the anastomosis by the end of ten days, something should be undertaken at once in order to keep nutrition at a proper level. Personally, I have found a jejunostomy for feeding to serve this purpose better than any other procedure. This must be done by exposing the distal limb of the jejunum accurately, either by reopening the original incision or by making a new one sufficiently wide for accurate exploration, since it is of the utmost importance to determine the exact loop of jejunum best suited to receive a jejunostomy tube. Ordinarily, this loop is at a point from 30 to 50 cm. below the stoma, and should be a coil that lies comfortably in the left flank. If one uses a No. 16 French whistle-tipped catheter for this purpose and holds it in place by two small purse-string sutures, the bowel will not be constricted sufficiently to interfere with fluid passing by this point, nor will there be quite so much danger of obstruction from other structures that become adherent to the area about the operative field. Placing a small bit of the left omentum, if it is available, between the bowel and the peritoneum is advantageous. The catheter should be brought out through a small stab wound in the left flank, and should have been accurately inserted for one third of its length into the distal limb of the bowel. Through such a tube one may return the aspirations from the stomach, along with desired food elements. Many nutritive solutions have been advocated, and the only necessary precaution is that the formula selected does not produce too much diarrhea. The diarrhea can be combated

by paregoric added to the feedings, as suggested by Graham.²⁰ The formula should contain a high content of protein, to which has been added a sufficient excess of the water-soluble vitamins. Patients under this regimen will hold their own, and in time the original stoma will function, thus furnishing the most ideal conditions for a permanent result. It is easy to become discouraged in some of these jejunostomies for feeding, since the patient may not gain in weight and it may be difficult to maintain the blood constituents at a normal level. Often about the time one thinks that some further operative procedure must be done in order to save the patient's life, the original stoma begins to function, and from that time on everything goes well. In 3 of my cases following a jejunostomy twenty-five to thirty-one days elapsed before the stoma functioned.

Anesthesia in gastric surgery is still a debated question, and Nupercaine (1:500) as a spinal anesthetic has gained in popularity. In localities or clinics where pulmonary postoperative complications are rare, this appears to be the ideal anesthetic. At the Massachusetts General Hospital, however, we have found that spinal anesthesia is followed by a fairly high percentage of pulmonary complications, so that we have continued to use novocain local and splanchnic block for gastric surgery. In several cases, by injecting a small amount of Evipal into the intravenous tube when the patient becomes tired or areas difficult to reach by local anesthesia are touched, we have caused the procedure to go smoothly and with little strain on both the surgeon and the patient. Also, it might be pointed out that when large quantities of novocain are used the barbiturates may be helpful as an antidote, in at least one case of novocain poisoning during gastrectomy, Evipal seemed to be a specific. Therefore, it would seem that its careful and guarded use as an adjunct to local and splanchnic block is justifiable. In a fairly large series of gastric operations done under local and splanchnic block, there have been no postoperative pulmonary sequelae. The patients have had a smooth convalescence, and few of the minor complications associated with general or spinal anesthesia have occurred. One death occurred that may have been due to novocain poisoning.

One of the most outstanding contributions of recent date is that of Pfeiffer²¹ on the management of gastrojejunal fistula. Reasoning that the poor nutrition of patients suffering from this condition was based on the fact that the fecal current came back into the stomach, rather than on a food loss due to the direct passage from the stom-

ach into the colon, he concluded that if the contents of the bowel could be shunted proximal to the stoma an improvement might be expected and a better and safer operative procedure could be eventually carried out on the original lesion. The results turned out much better than Pfeiffer had dared hope, his patients improved and gained weight. When a second operation was performed on the stoma three months later, the inflammatory reaction in the region of the fistula was very much less than usual. The shunting is accomplished by means of a complete right colostomy. This requires closure ultimately, but is a small price to pay for the added protection of a cleaner field in which to work. It is possible under these circumstances to do a subtotal gastrectomy with much greater safety at the time that the fistula is corrected.

CARCINOMA OF THE STOMACH

Livingston and Pack³² have published a small monograph on cancer of the stomach which has many interesting and surprising statistical tables. The authors compare the number of deaths in the United States from cancer of the stomach during the past fifteen years with those from highway accidents. According to their figures there have been 600,000 deaths during this interval from carcinoma of the stomach and 400,000 from highway accidents. They have also analyzed the figures from all clinics of large size where reports on this lesion have been published. The average five-year-cure figure for the country is only about 5 per cent. They point out that unless the effort is made no patient can be cured. The risk of gastrectomy may be high but this is the only procedure that offers any chance of cure. Clinics with high operative mortality in gastrectomy for cancer have on an average more five year cures from this disease than have clinics which show a low mortality. This seems to indicate that one should resect any stomach invaded by malignant disease which can be removed, regardless of the size or extent of the lesion, so long as the liver and peritoneum are not involved. Involvement of the lymph nodes is no contraindication to gastrectomy.

Parsons and Welch³³ have published a subsequent series of cases treated for carcinoma of the stomach at the Massachusetts General Hospital. They stress the importance of radical surgery for early lesions, and point out that of the few patients who have had resections for carcinoma in situ, all have lived over five years. An interesting and disarming feature is that patients who have had symptoms of a stomach disorder for one year or over have a much better chance for a five year

cure—if resection is possible—than do those who have had symptoms for six months or less. In other words, the rapidly growing lesion, although this may not be evident from pathological classification, may be suspected on the basis of duration of symptoms. These authors show that the resectability has been increased from 25 to 35 per cent, while the mortality from the operation has been reduced from 35 to 25 per cent during the second five year period reported on. They further point out that although there are more patients living for longer periods of time in their series than in Ogilvie's³⁴ they have the same percentage of living patients at the end of five years as he reports. One may well criticize palliative gastrectomy for cancer. The occasional cure and the frequently long respite as well as the psychological effect on the patient are important. Patients who have survived gastrectomy for cancer and die of recurrence have a more comfortable exitus than do those who die of starvation and nausea with the cancer unremoved.

So far, 38 total gastrectomies have been done at the Massachusetts General Hospital for cancer. These are discouraging cases in that the operative mortality was high and all the other patients eventually died of their disease. However, many long respites were obtained and a more comfortable exitus for those who survived the procedure.

Clute and Albright³⁵ have contributed a very important modification of the incision for high gastrectomy. They advocate a hockey stick incision which goes across the lower costal cartilages to the left of the midline. By dividing the costal cartilages, one gets a much better exposure of the region of the lower esophagus and diaphragm. We have found this type of incision extremely helpful in these high procedures.

ACUTE INTESTINAL OBSTRUCTION

McKuttrick and Sarris³⁶ have just reported the fourth series of cases with acute small-bowel obstruction from the Massachusetts General Hospital. The entire forty year period has been reviewed, the three previous decades were reported by Scudder,³⁷ Richardson³⁸ and McIver.³⁹ The use of the Miller Abbott tube in acute intestinal obstruction was critically reviewed in the most recent report. It was interesting to note that in all cases with acute small-bowel obstruction operated on within the first twenty-four hours of the disease, there were no deaths. The mortality rose sharply during the second twenty-four hours and reached 22 per cent. They state that, after forty-eight hours, it is obvious that more people will survive if a temporary conservative

regimen of intubation and emptying of the upper gastrointestinal tract is carried out. Patients thus become, after a period of twenty-four to seventy-two hours, better operative risks. McKittrick and Sarris recommend that a Miller-Abbott tube be passed as soon as a patient with acute small-bowel obstruction enters the hospital, a flat plate of the abdomen should then be taken in order to determine, if possible, the approximate location of the obstruction. If the patient has had symptoms for twenty-four hours or less, immediate operation should be undertaken. If symptoms have existed for forty-eight hours or more, conservative measures should be adopted. During the operation it is essential that continuous suction be applied to the Miller-Abbott tube, as the contents from the upper small bowel may continue to pass back into the stomach. This eliminates the danger of aspiration of stomach contents during anesthesia. The tube is left in place and kept there until the intestinal current is completely re-established. In patients operated on in the later stages, if the small bowel can be fairly decompressed by the Miller-Abbott tube prior to operation the hazard of operation is greatly reduced. As stated in the progress report¹ for last year, the use of iced drinks, as suggested by Dr. George W. Holmes, aids materially in getting the end of the tube through the pylorus.

FOREIGN BODIES IN THE GASTROINTESTINAL TRACT

DeBakey and Ochsner³³ have made an exhaustive study of foreign bodies within the intestine. They divide these into bezoars caused by the ingestion of hair, those produced by concretions—such as shellac—and another interesting type which they find very prevalent in the South and which is due to the ingestion of the fibrous portion of the persimmon—apparently the particles gather in a bolus which completely obstructs the lumen of the bowel. These authors also mention other forms of foreign bodies which produce obstruction, including masses of round worms. Gallstones may erode into the lumen of the bowel and produce the so-called gallstone ileus. It is generally the rule that these foreign bodies in themselves are not large enough to produce intestinal obstruction, but as they pass through the gastrointestinal tract become coated with solid

fecal matter, this often produces a concretion of sufficient size to cause obstruction. The commonest site of obstruction from foreign bodies is in the terminal ileum, since the small bowel gradually becomes narrower as the ileocecal valve is approached.

CASE RECORDS OF THE
MASSACHUSETTS GENERAL HOSPITALANTEMORTEM AND POSTMORTEM RECORDS AS USED
IN WEEKLY CLINICOPATHOLOGICAL EXERCISES

FOUNDED BY RICHARD C. CABOT

TRACY B. MALLORY, M.D., Editor

CASE 26071

PRESENTATION OF CASE

A twenty five year-old unmarried woman was admitted to the emergency ward complaining of abdominal pain of twenty hours duration

The patient stated that she was perfectly well during the day preceding admission she ate a hearty meal at 4 p.m. and then attended the cinema. Soon after returning home, however, at 11:00 p.m. she noticed the gradual onset of generalized, constant, abdominal pain which occurred with cramp-like exacerbations, and became steadily worse. At 3 a.m. she called her physician who prescribed pills "to make her vomit." This was successful in that she did vomit one hour later, with but slight relief. The pain continued unabated throughout the day of admission, but gradually became less severe in the afternoon a few hours before entry. The pain was then described as being steady, in the lower abdomen, sometimes more severe on the right side, sometimes on the left.

Her last catamenia began three days before admission, lasted only thirty six hours, and ended twenty four hours before the onset of the present illness. Characteristically her periods were regular occurred once every twenty six to twenty eight days, and usually lasted one week without dysmenorrhea. Prior to the last period there had been no previous aberration either in time, length or amount of flow. Bowel movements were described as being normal both before and during the present illness. There were no other symptoms. The family and past histories were non-contributory.

Physical examination revealed a well-developed and nourished woman who was experiencing acute abdominal discomfort. The abdomen was very slightly distended and tympanitic throughout, with slightly increased peristaltic sounds. There was tenderness with muscle spasm more marked in the lower abdomen especially on the right. Both the vagina and rectum were diffusely tender. No masses or fluid was noted. The heart and lungs were normal, and the remainder of the physical examination negative. The blood pressure was 124 systolic, 76 diastolic.

The temperature was 98°F., the pulse 110, and the respirations 25.

Examination of the urine was negative. The blood was normal except that there was a leukocytosis of 30,700.

A laparotomy was performed soon after admission.

DIFFERENTIAL DIAGNOSIS

DR. FRED A. SIMMONS. The first impression one gets from reading this history is that it was a surgical case and that the patient had an acute lesion in the abdomen, probably on the basis of ectopic gestation or appendicitis, both of which would demand operative interference. When one goes over the case again, however, the important findings are limited, I believe, to the fact that we have a twenty five year-old woman with abdominal pain and tenderness, a slightly rapid pulse and a markedly elevated white-cell count. In the absence of facts which do not appear in this record, one wonders why this patient needed to be operated on. I think if I had been called to see her or to discuss the case on the telephone without the advantage of my own physical examination, I should have said that she might have been observed for a while. I suppose it is fair to assume that the temperature was rectal because that is a routine procedure in the Emergency Ward. That might give some evidence that the patient was in shock. The pulse was slightly elevated and the respirations were elevated findings which might give us an inkling that she was experiencing air hunger. The problem assuming that it is a surgical emergency, resolves into two possibilities: sepsis in the peritoneal cavity and blood in the peritoneal cavity.

The past history of gastrointestinal symptoms is not contributory unless it rules out the possibility of her having had a gastrointestinal condition, with which I include appendicitis. She might have had a twisted ovarian cyst; this could account for the rapid pulse and the high white cell count but I should also expect fever. She might have had a ruptured dermoid cyst, which could have resulted in shock from the sudden discharge of necrotic material into the abdominal cavity. I am going to rule out gastrointestinal disease. If the history is correct, she might have had an ectopic gestation with the menstrual period limited to thirty six hours instead of one week. The history of the attack may be inaccurate and the menstrual history may not be a fact but I am going to rule out ectopic gestation in favor of a bizarre diagnosis, one I have not seen diagnosed preoperatively perhaps.

it is hazardous to make it. I believe that this girl who is unmarried and twenty-five and who, in my opinion, has blood in the abdominal cavity, had a chocolate endometrial cyst, which had become distended in association with menstrual flow and had eventually ruptured, thus resulting in a pelvis, if not an abdomen, full of bloody fluid.

DR FIORINDO A. SIMEONE: There is one bit of information, not in the record, which would have helped support Dr. Simmons's contention. We tapped the abdomen with an aspirating needle and obtained a few drops of bright-red blood. We were not certain this was coming from the peritoneal cavity, but we were reasonably certain there was no general peritonitis. She was operated on for the possibility of acute appendicitis or active bleeding into the peritoneal cavity.

She did have a ruptured left ovarian cyst, which we removed at operation. There was both clotted and free blood in the pelvis, indicating both old and recent bleeding.

CLINICAL DIAGNOSIS

Acute appendicitis?

Hemoperitoneum?

DR. SIMMONS'S DIAGNOSIS

Ruptured chocolate (endometrial) cyst of ovary, with hemoperitoneum.

ANATOMICAL DIAGNOSIS

Hemorrhagic pseudomucinous cystadenoma of the ovary, with spontaneous rupture.

PATHOLOGICAL DISCUSSION

DR. TRACY B. MALLORY: The cyst in question was lined with tall columnar epithelium, of the type we see ordinarily with a pseudomucinous cyst. The hemorrhage was obviously very fresh, with no changed or blackened blood such as is seen in a chocolate cyst. So I think we can rule out endometriosis. Why a pseudomucinous cyst should have hemorrhage into it and should have ruptured spontaneously, I cannot answer. The ovary as a whole was not infarcted, so that I do not believe there could have been a twisted pedicle. All that we can say is that she had a spontaneous rupture of an adenocystoma of the ovary.

DR. FRANCIS T. HUNTER: Was there quite a bit of hemorrhage?

DR. SIMEONE: We estimated about a pint of blood, a large part of which was clotted.

DR. HUNTER: I should like to mention a test devised by Dr. Raymond H. Goodale, of Worcester, which is helpful in the question of bleeding into the abdominal cavity. He finds that if

blood is taken in a dry syringe, preferably in duplicate from both antecubital veins, the normal individual's serum diluted to 1:17 no longer gives a positive guaiac test. If a lot of blood is being absorbed in the abdominal cavity, the test may be positive up to 1:50. The same may occur if there is much trauma or bruising.

DR. EDWARD B. BENEDICT: You can also diagnose hemoperitoneum very easily with the peritoneoscope.

CASE 26072

PRESENTATION OF CASE

A fifty-nine-year-old married Greek salesman was admitted complaining of backache and paralysis of the legs.

The patient had been perfectly well until two weeks prior to admission, at which time quite severe backaches developed in the lower dorsal and upper lumbar spine. There were no sharp pains, and the pain radiated to both sides. A diagnosis of "lumbago" was made, and the back strapped on two occasions without effect. About five days before entry the patient began to notice weakness in both legs, which rapidly progressed during the next three days to complete paralysis of both lower extremities. Numbness was present in both of them. He became unable to void but at no time had been incontinent. There was no history of trauma. He had always been constipated, but of late the constipation had increased to such an extent that cathartics were required. On a few occasions he had passed black stools, but no gross blood. The patient had had no headaches, vertigo, syncope or eye symptoms. He had not lost weight.

He was born in Greece but had lived in the United States for forty-five years. He had not been exposed to tuberculosis.

Physical examination revealed a well-developed and nourished man in no distress but unable to move his legs. The chest examination was negative. The blood pressure was 130 systolic, 85 diastolic. Abdominal and rectal examinations were negative. Examination of the spine was negative except that the patient complained of pain on motion in the region of the third and fourth lumbar vertebrae. Both lower extremities were without motor power. The knee jerks were active but not hyperactive. Scratching of the feet caused a mass reflex. The Babinski signs were weakly positive, and the cremasteric reflexes were absent. The upper abdominal reflexes were present, the lower ones absent. Sensation was absent over the legs and thighs to just above the groin in front and below the first lumbar nerve in back.

The bladder was paralyzed, and the anal sphincter weak.

The temperature was 98.6°F, the pulse 80, and the respirations 18.

Examination of the urine was negative. The blood showed a red-cell count of 4,040,000 with 75 per cent hemoglobin, and a white-cell count of 11,500 with 89 per cent polymorphonuclears, 7 per cent lymphocytes, 3 per cent mononuclears and 1 per cent eosinophils. The nonprotein nitrogen of the serum was 30 mg per 100 cc., and of the whole blood, 43 mg. A blood Hinton test was negative. A lumbar puncture showed an initial pressure of 120 mm. of water, no rise occurring even with combined jugular pressure. The spinal fluid was xanthochromic and contained 1 lymphocyte and 14 red cells per cubic millimeter. The total protein was 618 mg per 100 cc., and the gold sol curve 225554422, the Wassermann test was negative.

An x-ray of the dorsal and lumbar spine showed extensive spur and bridge formation about the margins of the bodies of the dorsal and upper lumbar vertebrae but no evidence of bone destruction. Lipiodol injected into the lumbar canal met a complete block opposite the body of the twelfth dorsal vertebra. The filling defect was an irregular point, more pronounced on the posterior and right sides. There was a questionable irregularity of the pedicle of the twelfth dorsal vertebra. X-ray films of the chest were negative.

On the third hospital day an operation was performed.

DIFFERENTIAL DIAGNOSIS

Dr. J. J. MICHÉLSEN Applying the old rule I shall first try to determine the site of this lesion. We are told by the patient that there was weakness in both legs which progressed rapidly to complete paralysis. On examination this was confirmed. There was a complete paraplegia of the legs. This paralysis was of the upper motor neuron type. There were positive Babinski signs and marked weakness, findings which indicate that the spinal centers for the leg movements were released from the cerebral control of the fibers carried in the pyramidal tracts. Other significant signs were the absence of lower abdominal reflexes, the presence of the upper ones and a sensory level, presumably for all forms, at the first lumbar segment. On the basis of these motor reflex and sensory disturbances, the lesion ought to be localized in the cord at the twelfth thoracic segment. There seems to be a complete transection of the cord at that level. Bladder paralysis, which is a sign of complete transection at any level, furnishes additional evidence for that pre-

sumption. Weakness of the anal sphincter cannot very well be explained on that basis and may be caused by some other process not related to the lesion here. The history also tells of constipation rather than of the fecal incontinence that would ordinarily go with weakness of the sphincter. But this point is of minor importance.

Surprisingly the x-ray findings after the injection of Lipiodol do not seem to confirm the clinical localization. There was a complete block opposite the body of the twelfth thoracic vertebra, the filling defect more pronounced on the posterior and right sides. This is a two-fold discrepancy. The level of the Lipiodol block was lower than that of the transection, and the block was more pronounced on the right side, a point which did not come out in history or findings. The level of the block corresponds with the upper sacral cord segments while the transection has to be localized at the twelfth thoracic segment opposite the ninth thoracic vertebra.

What type of lesion could give a mechanical block at one level and transection of the cord at another? The commonest lesions causing a complete block are tumors. There are intradural and extradural tumors. Intradural tumors arise within or outside the cord. The inconsistency of clinical and Lipiodol signs in this case may be in favor of such a lesion. In the pre-Lipiodol era the mistake of localizing a tumor too high was often made in intradural lesions. But everything else in our case is against this diagnosis. Even if for some reason or another the sensory examination could not be done accurately enough to bring out dissociation of the different types of sensation the history suggests that this diagnosis is not correct, inasmuch as a fairly acute onset is very unusual in cases with intradural tumors. The complaints about pain did not seem to correspond to segmental distribution so intradural tumors within and outside the cord probably can be ruled out.

Extradural lesions that cause block may arise from the dura, the structures in the epidural space or the vertebrae. There was vertebral disease in this case,—extensive spur and bridge formation about the margins of the bodies of the dorsal and upper lumbar vertebrae—but this spondylitis deformans cannot explain the neurological picture. There was no bone destruction. This rules out tuberculosis, osteomyelitis, syphilitic lesions of the vertebra and particularly tumor metastases. One point in the history should be mentioned, namely, that the patient had passed black stools on a few occasions. However, gastrointestinal cancers very rarely metastasize into the vertebrae, the common

primary tumors which do this are those of the breast, prostate and thyroid gland. On top of that the history tells us that the patient had not lost weight, and this would not fit into the picture of a tumor of the gastrointestinal tract with metastases to the spine.

Could it be a lesion of the epidural space? This was my first impression, and it still seems to me to be the best bet. This was based on certain features in the history and the inconsistency of the clinical findings and the Lipiodol block. Epidural lesions are apt to give a fairly rapid progression of symptoms. They extend farther up and down than do other tumors, and may cause circulatory disturbances with symptoms distant from the site of the block.

Epidural lesions which may cause block are tumors and inflammatory processes. In children the commonest tumor is sarcoma. In adults we look for granulomas, myelomas, hypernephromas and tumors due to echinococcus disease. The infectious tumors are tuberculous, syphilitic and pyogenic in nature. There is little evidence in the history and findings to support the diagnosis of any one of these, with one exception. Possibly the blood picture will give us a lead. The white count was increased, and there was a polymorphonucleosis. Since there was no evidence of systemic infection, these changes in the blood picture may indicate that the process in the epidural space was of pyogenic origin. On this basis we come to a diagnosis of an epidural abscess, and indeed the history and some of the findings are consistent with this diagnosis. Occasionally, epidural abscesses occur without any preceding bone or systemic infection. This patient's story of pain could be quite typical, pain on motion is consistent, but whether or not there was tenderness is not mentioned. There was no increased temperature, and no leukocytosis in the spinal fluid—both factors somewhat against this diagnosis.

Summarizing, I should say that this case presented a clinical picture of transection of the cord at the twelfth thoracic segment and a Lipiodol block at the upper sacral segments caused by an epidural lesion. The type of this lesion cannot be determined with accuracy. Some features are

consistent with an epidural abscess, others are not. Another distinct possibility is epidural tumor.

CLINICAL DIAGNOSIS (PREOPERATIVE)

Extramedullary malignant tumor, compressing the cord at the twelfth thoracic segment

DR. MICHELSEN'S DIAGNOSIS

Epidural disease with transection of the cord
Epidural abscess?
Epidural tumor?

ANATOMICAL DIAGNOSIS

Plasma-cell myeloma of eleventh thoracic vertebra, with intraspinal, epidural extension

PATHOLOGICAL DISCUSSION

DR. TRACY B. MALLORY. Opinion on the wards was in essential agreement with that of Dr. Michelsen. It was believed that the patient had a transverse myelitis due to pressure from some intraspinal but probably extradural mass. Although the probabilities seemed somewhat in favor of a tumor, the failure to demonstrate positive evidence of cancer locally or elsewhere in the body made exploration obligatory. Dr. James C. White centered his operation at the level of the eleventh thoracic vertebra. As soon as the laminae were exposed it was evident that they had been extensively infiltrated by tumor. The right one in particular was very soft and rongueured away with extreme ease to reveal a dense plaque of tumor tissue covering the dura. A frozen section was reported "highly malignant tumor, probably carcinoma." Further exploration showed extension of the tumor in both directions, hence the laminae of the tenth and twelfth thoracic vertebrae were removed in order to give adequate decompression, and a portion of the tumor was cut away. There was no intradural extension. Better sections from the fixed material showed that the tumor was a plasma-cell myeloma rather than metastatic carcinoma. Following operation, no treatment was instituted, though with little optimism since most myelomas are relatively radio-resistant. Up to the time of his transfer to a cancer hospital there had been no detectable improvement.

PREMARITAL EXAMINATIONS

A PREMARITAL blood test for syphilis is a valuable procedure of modern preventive medicine. If positive, it serves to prevent infection of the prospective partner and provides an opportunity for adequate treatment of the infected individual, thus decreasing the possibility of bearing syphilitic children and of the later development of serious forms of the disease. A law to compel this procedure should not be necessary, but seven states have so legislated. That these laws have resulted in the discovery of 3300 cases of syphilis is indicated in an article by Dr. R. A. Vonderlehr in this issue of the *Journal*. The fact that by this discovery many individuals have been prevented from having the disease amply justifies the procedure. Such laws have engendered much discussion, and an able presentation of both sides of the question¹

has recently appeared in the *Journal of the American Medical Association*.

But the blood test alone is not enough. There is need for equal emphasis on physical examination, for the blood may not be positive in the early and infectious lesions of the primary stage, in certain partly treated cases or in the late stages of the disease. At the same time, evidence of the reliability of blood tests for syphilis is accumulating. Dr. Vonderlehr points out that modern serological tests properly performed will detect from 80 to 90 per cent of all cases of syphilis, with a very small percentage of false positives. The perfection of these tests has been largely due to the efforts of the Committee on Evaluation of Serodiagnostic Tests for Syphilis, which has conducted evaluation tests since 1935. It is vitally important that such tests be performed in all laboratories in accordance with the highest standards of excellence, which demand strict adherence to proved techniques. To accomplish this object the United States Public Health Service has published a manual of revised techniques.² In this handbook the originators of the tests have prepared detailed directions of how to conduct these procedures.

As with any laboratory procedure, physicians must interpret the report, realizing that a single positive report does not always mean syphilis and that a single negative report does not exclude syphilis. There should be an adequate physical examination, and a re-checking of all those with positive reports or with a history or manifestations suggesting syphilitic infection. Adequate provision for the follow-up of such individuals is essential for complete success.

Premarital blood-test laws will undoubtedly be enacted in other states in response to public demand. It is imperative that physicians and the public health authorities develop the necessary measures for the control of conjugal and congenital syphilis so that the individual and the community may reap the fullest benefits of medical knowledge accumulated over a period of years.

A STUDY OF ALCOHOLISM AND ITS ASSOCIATED PSYCHOSES

LAST fall, the Research Council for the Advancement of Science approved a program for attacking the problem of alcoholism and the psychoses incident thereto. Grants of financial aid for this movement have been made by three organizations: one by the Carnegie Corporation for a survey of all work done to date on the effects of alcohol on human beings, sponsored by the Department of Psychiatry of the College of Medicine of New York University, and under the supervision of Dr Norman Jolliffe, another by the American Philosophical Society for a study of the toxic factors of alcoholism, to be conducted at the New York Psychiatric Institute under the direction of Dr George A Jervis, and the third by the Dazian Foundation for Medical Research to carry forward research work on the role of alcohol in liver cirrhosis, which will be performed at the College of Medicine of New York University. These studies will continue through 1941 and are designed to fill any gaps in investigations hitherto conducted and to stimulate further research in the problems involved. The information acquired will be published after the completion of these studies.

Dr Karl M Bowman, chairman of the council and director of psychiatry at Bellevue Hospital, has pointed out that the long-range objective of the council is to discover the etiology of alcoholism and better methods for its prevention and treatment. He believes that this disease and the incidental psychoses constitute one of the great public-health problems of modern times, particularly because no systematic attack on this menace to health comparable with those relating to tuberculosis, cancer, syphilis and heart disease has been attempted.

Since alcoholic beverages of one form or another will always be demanded by the inhabitants of this country, since they are now generally procurable and since voluminous advertisements of the distillers and brewers are alluring, existing conditions present a challenge to preventive and therapeutic medicine, for it is generally acknowledged that alcohol, where improperly used, has toxic properties

Social, economic and political questions relating to the use of alcohol have been topics for discussion since the early history of mankind but are not included in the program outlined by the council. In 1932 a book was published under the title of *Alcohol and Man*. This was edited by Haven Emerson, M.D., Henry A. Christian, M.D., Reid Hunt, M.D., Arthur Hunter, LL.D., Charles C. Lieb, M.D., Walter R. Miles, Ph.D., and Ernest G. Stillman, M.D. It was regarded as the last word on the subject from a medical standpoint and was intended to consider many of the problems included in the plan of the new council. Articles in this book were contributed by three of the editorial group and twenty others, including practitioners, pathologists, psychiatrists and statisticians, all holding important positions in their respective fields. Even so, the progress of medicine has been so rapid in recent years that it is reasonable to expect that up-to-date contributions to the recorded facts and conclusions of six years ago may increase our knowledge and lead to organized efforts directed toward the prevention and control of alcoholism. That it is a matter of vital concern is beyond doubt. The *Journal* has published articles relating to the problem from time to time, thus demonstrating an appreciation of its importance and a concern in the sentiment that it should be dealt with through a well-organized public-health program.

MEDICAL EPONYM

BARANY TEST

The caloric test was described by Robert Bárány (1876-1936), then assistant to Adam Politzer in the otological clinic at the Royal University in Vienna, in an article entitled "Untersuchungen über den vom Vestibularapparat des Ohres reflektorisch ausgelosten rhythmischen Nystagmus und seine Begleiterscheinungen [Studies in the Reflex Rhythmic Nystagmus and Accompanying Phenomena following Stimulation of the Vestibular Apparatus of the Ear]" published in the *Monatschrift für Ohrenheilkunde* (40: 193-297, 1906). The translation of a portion of the article is as follows:

I have systematically investigated the nystagmus occurring when the ears are syringed, and have observed several previously unknown effects. I use only Hartmann's attic syringe, introducing it close up to the in-

tact drum, or if the drum is perforated directly into the perforation, or where total destruction exists as the result of radical operation clear up to the wall of the labyrinth. The water to be used is drawn into a No. 110 Politzer bag the temperature having been noted. The bag is connected with an attic syringe by means of a rubber tube 75 cm. in length. The syringe having been introduced into the canal it is held in place with one hand and the patient's face is turned toward the operator. An assistant compresses the bag. The phenomena which I have observed are as follows: If the right ear is syringed with water lower than body temperature while the head is held erect, there occurs a nystagmus to the left, predominantly rotatory, but nearly always with a horizontal component. This is strongest when the eyes are directed toward the left weakest toward the right. This nystagmus occurs when the vestibular apparatus is intact even when the drum is unbroken. The lowest temperature required was 12 C. The nystagmus lasts for about one and one-half to two minutes. If water warmer than body temperature is used, nystagmus occurs in a direction opposite to that following the injection of cold water. That is on syringing the right ear nystagmus, predominantly rotatory is directed to the right and is most marked when the eyes are turned right. With intact drums, however nystagmus even after the highest tolerable temperature (51 C.) is often not very marked.

SECTION OF OBSTETRICS AND GYNECOLOGY*

FATAL SEPSIS FOLLOWING NORMAL DELIVERY

Mrs K., a twenty four year-old primipara, entered the hospital in labor on February 8 1934. Owing to language difficulties, no history whatever was obtained. She had apparently received no antepartum care.

Examination showed a well-developed and nourished woman. The temperature was 98.4°F., the pulse 82. The blood pressure was 110 systolic 60 diastolic. The heart sounds were clear and regular, there were no murmurs. The lungs were clear throughout and of uniform resonance. The pregnancy appeared to be at full term, with the fetus lying in an OLA position. The fetal heart rate was 142, and the sounds were clear and regular. Rectal examination showed the os one finger dilated and the head well engaged.

Labor progressed rapidly to a normal delivery

four hours later. The baby, a girl weighing 7 pounds, 8 ounces, was in good condition. The placenta was expressed twenty five minutes later, some difficulty was experienced in delivering the placenta, but it appeared to be intact on examination. The uterus contracted well, and there was no excessive bleeding.

The first three days of the puerperium were uneventful. The temperature remained normal, and the pulse rate never rose above 84. On the evening of the third day the temperature rose to 100.0°F. The patient complained of a cough and a little pain in the right chest. Examination showed nothing to account for the symptoms. There was some dysuria, and examination of a catheter specimen of urine was done, which showed a slight trace of albumin, a slight reaction of Benedict's solution and a sediment containing innumerable pus cells. The temperature remained elevated. The blood showed a white cell count of 22,000. Physical examination was negative, there was no tenderness over the kidneys. Urinary antiseptics were given, but with out effect on the temperature.

On the seventh postpartum day the patient passed several blood clots and the lochia became somewhat foul, there was also a piece of tissue which resembled decomposed placenta. The temperature, however showed no downward tendency following the expulsion of this material.

On February 17 nine days post partum, the temperature was 102.4°F., the pulse 102, the hemoglobin 35 per cent, the red-cell count 1,500,000 and the white-cell count 18,000. A blood culture was taken and yielded *Streptococcus haemolyticus*. The lochia was still slightly foul and a small piece of macerated placenta was removed from the cervix. The uterus was somewhat subinvolved but the vaults were free. A transfusion of 500 cc. of citrated blood from a compatible donor was given. Following transfusion both temperature and pulse dropped. The temperature remained normal for forty-eight hours, and the pulse was below 100.

On the twelfth postpartum day the temperature again jumped to 103.4°F. The white-cell count was 36,000 and the red-cell count 1,660,000. A second transfusion of 500 cc. of citrated blood was given. The following morning the temperature dropped to normal but rose to 105.0°F. in the evening and never again fell below 102.0. The pulse rose steadily, and the general condition declined. Vomiting occurred and distention appeared. Daily intravenous administrations of glucose were given to keep up the body fluids. The patient failed steadily, became delirious and later coma rose. The pulse could not be felt a few hours

*A series of selected case histories by members of the section will be published weekly. Comments and questions by subscribers are solicited and will be discussed by members of the section.

before death on February 25, seventeen days post partum. There was no autopsy.

Comment This is an interesting case of proved hemolytic streptococcus infection. It did not appear quite so early after delivery as such infections usually do. In view of the fact that some placental tissue was retained, it is barely possible that the infection was superimposed. The appearance of pus in the urine, in view of the positive blood culture, is suggestive of a renal infection of hematogenous origin. The uterus was left alone, the patient was treated very conservatively. Because of the marked anemia two transfusions were given. One does not expect that a high temperature will drop to normal and remain so for forty-eight hours from transfusion alone. Probably the drop in temperature following the second transfusion was merely characteristic of the infection and had nothing whatever to do with the transfusion itself, as the temperature immediately rose to 105.0°F and remained elevated until death. Chemotherapy—the use of sulfanilamide—might have been curative. There is no record that a uterine culture was taken, but in the presence of retained and infected placental tissue the inference is that the infection entered through the uterus.

ANNUAL PRIZE FOR INTERNS

The attention of interns in Massachusetts hospitals is called to the fact that a prize of \$50.00 has been offered by the Massachusetts Medical Society for the best written and most comprehensive case report submitted by one of their number holding an internship in any Massachusetts hospital which is approved by the American Medical Association for intern training during 1938–1940.

This report is to be typewritten, and when completed is to be sealed, unsigned, in a plain envelope, which in turn is to be placed together with a separate slip bearing the name and address of the contestant, in a larger envelope, and sent to Committee on Medical Education and Medical Diplomas, Massachusetts Medical Society, 8 Fenway, Boston.

The contest this year closes May 5, 1940. Reports may be submitted at any time prior to that date.

DEATHS

CHENEY—ROBERT C. CHENEY, M.D., of Boston, died February 8. He was in his forty-sixth year.

Born in Brookline, the son of Dr. Frederick E. Cheney, he attended Noble and Greenough School and Harvard University and received his degree from the Harvard Medical School in 1919. He served internships at the Massachusetts General Hospital and the Massachusetts Eye and Ear Infirmary.

Dr. Cheney was a fellow of the Massachusetts Medical Society, the American Medical Association and the New England Ophthalmological Society.

His widow, his mother and a brother survive him.

THOMPSON—CHARLES A. THOMPSON, M.D., of Newton, died February 3. He was in his sixty-eighth year.

Born in Upper Sackville, New Brunswick, he received his degree from the College of Physicians and Surgeons, of Baltimore, and took a postgraduate course at the Harvard Medical School before he started practice.

He was a member of the Massachusetts Medical Society, the American Medical Association and the Newton Medical Club.

His widow, three daughters, three sons and a brother, Dr. James B. Thompson, of Needham, survive him.

MISCELLANY

SPONTANEOUS PNEUMOTHORAX

Older writers, having observed that spontaneous pneumothorax was sometimes followed by arrest of pulmonary tuberculosis, were tempted to regard this phenomenon as one of nature's haphazard attempts to cure. The serious results, however, far outweigh the occasional beneficial results—spontaneous pneumothorax is a traumatic accident to be avoided if possible. Recent studies directed toward the underlying cause of spontaneous pneumothorax are reawakening interest in the subject and those of Charr (Spontaneous pneumothorax. *Am Rev Tuberc* 40:565–570, 1939) are of particular interest.

Ten cases of fatal spontaneous pneumothorax are reported. All cases were in the third and fourth decades of life, 6 were in men and 4 in women. Eight had pulmonary tuberculosis and 2 anthracosis.

In all, the onset of the pneumothorax was sudden, and it occurred while the patients were in bed. In none of the cases severe coughing, sneezing or any other form of physical exertion preceded the fatal accident. The chief complaints were dyspnea and pain in the same side of the chest as the pneumothorax. All showed cyanosis, clammy skin, weak pulse, dry mucous membrane of the mouth with thirst and apprehension of impending death.

At necropsy, it was found that in 7 of the cases the pulmonary rupture was in the midaxillary aspect of the upper lobe, and in 3 it was on the anterior surface about the midclavicular line. In 2 of the latter group the rupture was in the upper lobe and in 1 in the lower lobe. In all the perforation was either in the front or the axillary region of the lungs—in none on the posterior surface of the lung.

In 3 cases with the rupture on the anterior surface of the lungs, the perforation took place through the center of large and acutely caseous tuberculous nodules, measuring about 1.5 cm. in diameter. The visceral pleura covering them was thin and transparent without adhesions to the adjacent parietal pleura. Following the ruptures deeper into the lungs led into irregularly shaped and acute cavities in the center of caseous consolidation. The cavities varied in size and were located in the anterior half of the lungs. Projecting into the cavities were several stumps of bronchi and many cord-like structures criss-crossing the cavities, which on section proved to be the remnants of lung tissue. Excursion of the air through these bronchial stumps was free. When the air was rapidly pumped into the main bronchi, the perforated visceral pleura covering the caseous nodules ballooned out remarkably. The surface distribution of the caseous tubercles in these 3 cases was interesting. Practically all the acutely caseous tubercles were on the anterior portions of the lungs.

The posterior parts showed principally congestion and areas of gelatinous pneumonia.

In 7 cases with the ruptures in the axillary region the character of the ruptures differed from those already described. In none did the perforation take place through the center of caseous tuberculous nodules as in the previous cases. There was much pleural thickening about the ruptures. The tuberculous which was present in all excepting 2 anthracosislike cases was chronic in form with considerable fibrosis throughout the lungs. Although there were scattered caseous tubercles, many of them showed on histological examination fibrous capsules surrounding them. Furthermore none of these cases showed superficial tubercles as acutely caseous as those in the first 3 cases.

It seems that the immediate cause of the pulmonary rupture in these 7 cases may have been tugging on the pleural adhesions. There is considerable vertical excursion of the lungs due to the greater depth of the costophrenic angle at that point. The sliding motion of the lung upon the inner surface of the thorax is probably most marked along the axillary aspect of the chest which if that is the case, accounts for the marked tugging movement in the pleural adhesions along the axillary region.

The absence of pulmonary rupture on the posterior aspect of the lungs confirms the belief that the cause of spontaneous pneumothorax is largely a mechanical one. The front and the axillary portions of the thorax move more in respiration than the posterior parts where the ribs are attached to the spinal column. These factors of chest movement may be more pronounced when a person lies on his back.

The left side is more frequently involved than the right, the percentage being approximately 60 on the left and 40 on the right. Various theories have been advanced to account for left-sided preponderance but there seems to be no doubt that the heart action produces an additional pulmonary mobility on the left side.

Spontaneous pneumothorax occurs in diseases other than tuberculosis. In the author's present series, 2 cases had far advanced anthracosislike uncomplicated by tuberculosis. In one of these there were large emphysematous blebs in the midaxillary region of the upper lobes rupture of which very likely produced the pneumothorax. Over these blebs the visceral pleura was considerably thickened, but the microscopical examination of the walls of the blebs showed extreme thinning of the elastic layer and at several points there was an actual breach to the continuity of the elastic lamina. In the other case the perforation of the lung was due to an extension of a cavity located in the center of a large anthracosislike mass in the right upper lobe.

Morphological changes of shock and related capillary phenomena were noted. These changes were marked diffuse congestion of capillaries and venules, especially in the lungs, liver and kidneys. Many of the alveolar spaces were filled with edematous fluid, and the capillaries were filled with blood. Supportive treatment usually employed in shock, in addition to withdrawal of air from the pleural space, which of course, is most important may be of value. Wrapping the patient with blankets, giving hot drinks and oxygen and the intravenous administration of fluid may be helpful though Moon has warned that too much heat produces peripheral vasodilatation and loss of body fluid in the form of perspiration which may aggravate shock. — Reprinted from *Tuberculosis Abstracts* (February 1940)

NOTES

Fourteen men have been granted traveling fellowships fellowships and scholarships, totaling \$8650 by the Harvard Medical School it was recently announced at Harvard University. These awards, for the coming academic year are as follows: Edward Hickling Bradford Fellowship to Walter R. MacLaren of Williamstown Massachusetts; John White Browne Fellowship to Samuel Lewis, D.M.D. 35 of Rosedale New York; William O. Moseley Jr., Traveling Fellowship to Paul C. Zamecnik, M.D., 36 of Cleveland Ohio; Jeffrey Richardson Fellowship to Sinclair H. Armstrong Jr., M.D. 37 of New York New York; Whitman Fellowship and Dr. William Hunter Workman Fellowship to Nathan B. Talbot, M.D. 36 of Brookline Massachusetts; Dr. William Hunter Workman Fellowship to Nathaniel B. Kurnick, M.D., of Brooklyn, New York; James Jackson Cabot Fellowship to Hubert W. Smith, M.D., of Dallas Texas; DeLamar Student Research Fellowships to William R. Christensen, M.D. of Salt Lake City Utah; Henry S. Fuller, M.D. of Washington District of Columbia; John W. Kirklin, M.D. of Rochester Minnesota; and Irving M. London, M.D. of Malden Massachusetts; Charles Eliot Ware Memorial Fellowship to Herbert R. Morgan, M.D. of Bell California; George Cheyne Shattuck Memorial Fellowship to Thomas H. Weller, M.D. of Ann Arbor Michigan; John Ware Memorial Fellowship to Joseph M. Foley, M.D. of Dorchester Massachusetts.

Dr. S. Walter Ranson, professor of neurology and director of the Neurological Research Institute at Northwestern University since 1928 has been appointed Edward K. Dunham Lecturer at the Harvard Medical School for the current academic year. He will deliver a series of lectures on March 4, 6 and 8 which are open to all interested professional persons.

At the annual reunion dinner of the Boston University School of Medicine Alumni Association, Dr. Milo C. Green of Boston a member of the twenty-five year class, was elected president. The other officers chosen were as follows: vice-presidents Dr. Harold L. Leland of Lowell and Dr. John M. Wilcox, of Woburn; secretary, Dr. Frank E. Barton, of Boston; treasurer, Dr. Harold W. Ripley of Braintree; directors (for three years) Drs. Rudolph Jacoby and Samuel N. Vose of Boston.

CORRESPONDENCE

MIDDLESEX ALUMNI FUND

To the Editor—The Graduate Association of Middlesex University School of Medicine has complied with Part I of the new fund contract as set down in the stipulations of Dr. Elliott P. Joslin. There is on deposit in cash at the Boston Safe Deposit and Trust Co. more than the \$30,000 required as of February 1, 1940.

H. L. MUGRAVE, M.D., *President*
M. L. KRAFT, M.D., *Secretary*

ARTICLES ACCEPTED BY THE AMERICAN MEDICAL ASSOCIATION COUNCIL ON PHARMACY AND CHEMISTRY

To the Editor—In addition to the articles enumerated in our letter of December 6 the following have been accepted:

Abbott Laboratories

- Sterile Solution Thiamin Chloride—Abbott, 250 mg, 5 cc bottle
- Sterile Isotonic Solution Thiamin Chloride—Abbott, 100 mg, 10 cc. bottle
- Tablets Thiamin Chloride—Abbott, 6 mg

Cutter Laboratories

- Sobisminol Mass—Cutter
- Sobisminol Mass—Cutter, capsules
- Sobisminol Solution—Cutter
- Sobisminol Solution—Cutter, 1 cc ampules
- Sobisminol Solution—Cutter, 2 cc. ampules

Eli Lilly & Company

- Combined Diphtheria Toxoid Tetanus Toxoid, Alum Precipitated, two 1 cc vials package
- Combined Diphtheria Toxoid Tetanus Toxoid, Alum Precipitated, one 10 cc vial package
- Sobisminol Mass—Lilly
- Pulvules Sobisminol Mass—Lilly
- Sobisminol Solution—Lilly
- Sobisminol Solution—Lilly, 1 cc ampules
- Sobisminol Solution—Lilly, 2 cc. ampules
- Sobisminol Solution—Lilly, 50 cc. ampules

E R Squibb & Sons

- Sobisminol Mass—Squibb
- Sobisminol Mass—Squibb, capsules
- Sobisminol Solution—Squibb
- Sobisminol Solution—Squibb, 1 cc ampules
- Sobisminol Solution—Squibb, 2 cc ampules
- Sobisminol Solution—Squibb, 50 cc ampules
- Epinephrine in Oil—Squibb

PAUL NICHOLAS LEECH, *Secretary*

535 North Dearborn Street,
Chicago, Illinois

REPORTS OF MEETINGS

NEW ENGLAND PATHOLOGICAL SOCIETY

At a meeting of the New England Pathological Society at the Peter Bent Brigham Hospital on November 16, Dr Sidney Farber introduced Dr Paul R. Cannon, professor of pathology at the University of Chicago, who spoke on 'The Relation of Flocculating Antibodies to Tissue Hypersensitiveness and Localized Disease'

Dr Cannon and his collaborators set out to determine whether a true correlation existed between the intensity of local tissue reaction in the Arthus phenomenon and the titer of circulating antibodies. Opie, who had done most of the competent earlier work in this field, believed that the tissue injury was a local anaphylactic process whereby the vital organs were spared a general anaphylactic shock. Although he never made any final statement due to his inability to obtain consistent correlation between the intensity of the local reaction and the antibody titer, Opie was aware that the demonstrated precipitins were not necessarily the same as the demonstrable ones, and felt that there probably did exist a true correlation of the two factors in the Arthus phenomenon. Culbertson, by employing the gravimetric method of Heidelberger and Kendall which measures antibody content rather than titer, did find a direct parallelism between the skin reaction and the amount of antibody. Several reputable workers, however, had been unable to corroborate this work and were of the opinion that tissue hypersensitivity was more permanent than precipitin formation and that there

was no direct relation between the two factors. Two reasons for the contradictory results, Dr Cannon concluded, lay in the use of the unreliable method of antigen dilution for titrating the antibody and in the use of complicated protein antigens.

Consequently, the precepts were laid down in Dr Cannon's work that a pure protein, such as crystalline egg albumen, and a reliable method for determining the amount of antibody should be employed. The method consisted of adsorbing the antigen on collodion particles and of testing the agglutination of these particles by using the centrifugalization and resuspension method. The amount of resuspension is inversely proportional to the amount of antibody present. By this method, a direct correlation between the Arthus reaction and the content of circulating antibodies was consistently found. The sensitivity of the method was demonstrated by detecting precipitins in serum where none could be found by antigen-dilution tests. The use of desensitizing doses of antigen caused a disappearance of the skin reaction, whereas the precipitins have never been found absent. On the other hand, in passive sensitization the removal of precipitins by adsorption on egg albumen caused a concomitant fall in the intensity of the skin reaction.

As further support for his theory of a direct correlation between the local manifestation and the general antibody content, Dr Cannon cited the oft repeated experiments on the injection of various organisms into non immune and immune animals, with the characteristic findings at the local site. An interesting additional experiment cited was that of Frisch, who had shown that the number and character of pneumococci in the sputum reflect the status of the circulating antiserum.

In summary, Dr Cannon made a plea for further study of the early effects of flocculating antibodies. He stated that it was their presence and that of precipitins which, together with the increase in phagocytes, promote tissue sensitivity and offer protection. A second function of these antibodies is their role in the fundamental mechanism for mobilizing and destroying foreign parenteral proteins in order to maintain the integrity of the host's protein. Occasionally their adverse effects are manifest due to toxic by-products which cause serum sickness, allergy and so forth. Dr Cannon emphasized that such untoward events do not signify that the mechanism is fundamentally faulty, for although the organism may at times be harmed or destroyed, the phenomenon in its fundamental form is protective for the race.

Dr Valy Menkin opened the discussion by suggesting that the content of antibody in the tissues might conceivably differ from that in the circulation. In regard to the mechanism of the local reaction, he stated that any non specific infection will be fixed at the local site by the process of inflammatory fixation through the presence of lymphatic blockage. This would be reinforced by the precipitation of the antigen antibody complex. He mentioned the Koch phenomenon as an example of local reaction without antibodies. By the use of a concentrated urea solution, he had been able to dissolve the fibrin barrier and to prevent the local fixation, even in the immune animals. He questioned whether the use of such a reagent, together with the antigen injected, might not cause precipitation of the complex to occur in the blood or vital organs with a general rather than local anaphylaxis.

Dr Tracy B. Mallory stated that he did not believe the Arthus phenomenon was a prototype of hypersensitivity and immunity as a whole. The rabbit is a good antibody producer and an animal in which a good Arthus

reaction can be obtained, whereas the guinea pig is extremely poor in both regards, although easily made hypersensitive. In the latter absence of antibodies is demonstrable not only by direct measurement but by failure of passive transfer to prove effective.

Dr. Louis Dienes stated that in guinea pigs the histologic changes develop at the site of reinjection before the appearance of precipitins in the circulating blood and before the animal is sensitive to anaphylaxis. He concluded that in various species a different phase of hypersensitivity may be predominantly developed. In man it is the pre-anaphylactic phase, while in the rabbit a later phase which corresponds to the Arthus phenomenon is highly developed. Results obtained in studies on the Arthus reaction in rabbits do not necessarily apply to those in human beings.

Dr. Cannon replied that his main purpose was to improve the method for studying the problem. In answer to Dr. Menkin he stated that the difference suggested was merely one of time and that the inflammatory fixation might be inaugurated by the antigen-antibody reaction. In rebuttal to Dr. Mallory's criticism Dr. Cannon stated that a good Arthus reaction and measurable antibody content had been obtained in guinea pigs by carefully helping them to survive the early period of dangerous anaphylaxis. He said that another reason for variations in such reactions as the tuberculin test is the presence of multiple antigens of varying diffusibilities. In regard to its human application the speaker cited one case of a massive Arthus reaction with elevated precipitins in a child who had received diphtheria antitoxin. There have been twelve such reports. Furthermore, it has been shown that the effect of the injection of foreign serum in the human beings is inversely proportional to the intensity of the local reaction.

Dr. Cannon concluded that all the reactions of hypersensitivity may prove fundamentally the same if proper methods are used to minimize the apparent variation of results.

ALPHA OMEGA ALPHA LECTURE

On November 17 the Harvard Chapter of Alpha Omega Alpha, with John Hickham presiding had Dr. A. Elvehjem, professor of biochemistry at the University of Wisconsin, as the guest speaker. The title of his talk was "The Biological Significance of Nicotinic Acid." In reviewing the historical background of the vitamin B complex, the speaker called attention to the fact that nicotinic acid unlike the other components, is a well-known compound of relatively simple chemical structure. It was first obtained in 1867 by Huber who oxidized nicotine, while Funk in 1912 crystallized it from yeast. The latter found it useless in combating fowl polyneuritis but showed it apparently favored digestion and growth. No other biological significance was attached to nicotinic acid until Warburg and Euler demonstrated in 1935 its relation to coenzymes.

As for pellagra it was not until 1930 that Goldberger definitely established that the disease was caused by a food deficiency which he identified as being the heat-labile component of vitamin B. It was in that same year that these investigators, as well as Spies, demonstrated that the value of liver extract as a source of this substance was even greater than that of brewers' yeast. Dr. Elvehjem used chicks instead of the resistant rat and showed that the pellagra-like disease could be cured with liver extract minus riboflavin while the latter alone was not efficacious. It was soon demonstrated, however that this was no true pellagra and that the preventive factor

was a substance closely allied with nicotinic acid—namely pantothenic acid. This led to the adoption of black tongue in dogs as the disease of choice in experimentation and it was shown by the group at Wisconsin as well as by others, that riboflavin was not the effective component in liver extract.

The importance of nicotinic acid in the prevention and cure of pellagra in all its manifestations has been amply proved by many investigators, notably by Spies. The stomatitis, dermatitis, diarrhea and vague complaints of ill-being all disappear under appropriate therapy. Satisfactory improvement has also been claimed in non-specific stomatitis, gastrointestinal dysfunction and central nervous-system disorders. Many of the patients with the latter symptoms however require additional substitution therapy and invariably do better when the nicotinic acid is accompanied by other members of the vitamin B complex and this probably holds for many other cases of pellagra the speaker stated. It was suggested that nicotinic acid be used only in emergencies and that all pellagrins be put on adequate diets, possibly supplemented by this substance.

Dr. Elvehjem then discussed the distribution of nicotinic acid in tissues. There was considered to be no accurate chemical method for assaying the amount of material present. So far as bio-assay was concerned, it was determined that the most satisfactory animal was the dog and the response of canine black tongue has been the indication of potency used by Dr. Elvehjem. Estimating the daily human requirement of nicotinic acid as 25 mg., it was calculated that one should eat 100 gm. of fresh liver or about half a pound of lean meat which was found to contain about half as much of this factor as liver. The only substances supplying sufficient nicotinic acid in one feeding to elicit a response in canine black-tongue were animal tissues and yeast.

In order to determine the efficacy of related compounds, various pyridine derivatives were tested both in the dog and by bacterial growth. The results indicated that only the acid, the amide and those compounds capable of conversion by simple processes within the body to these specific chemical structures were capable of substitution. The use of pyrazine compounds in human pellagra has been favorably reported by Spies, but Dr. Elvehjem has found their effects to dogs to be evanescent. He suggested that these substances could probably replace nicotinic acid from the more vital tissues and that the ultimate failure of response was indicative of a replacement of all available nicotinic acid from these sources.

The toxicity for animals has been demonstrated to be very low but the occurrence of heat and angling in the human being treated with as little as 20 mg. is a real and constant manifestation of its action. The speaker advised however that therapy should not be curtailed on account of these transient symptoms which do not prove dangerous to the patient's eventual prognosis.

The function of nicotinic acid seems to be intimately associated with coenzymes "1" and "2" which were shown to contain the compound. Euler reported a decrease in the cozymase content of deficient rats, but these were not considered uncomplicated deficiencies. Dr. Elvehjem, using Euler's method, demonstrated essentially the same values for the dog and rat despite the definite difference in clinical response to a lack of nicotinic acid. Furthermore, the blood content was equivalent in both healthy and deficient dogs. Vilter and Spies on the other hand found the blood values by a different method to be decreased in pellagrins while Knhn found no difference in the diseased state but an increase on feeding nicotinic acid.

On assay of the tissues, however, Dr Elvehjem did find a constant decrease in the cozymase content of the liver and muscles of deficient dogs. The use of purified cozymase supplied by Euler gave essentially the same results. Since these were the tissues richest in the coenzyme, it was suggestive that herein might lie the cause of the symptoms. An attempt to correlate the cozymase and nicotinic acid content of the same tissues resulted in only suggestive findings, but Dr Elvehjem attributed at least part of the difference to the use of an extraction method for cozymase which has subsequently been vastly improved and also to the fact that coenzyme "2" accounts for part of the nicotinic acid.

In summary, Dr Elvehjem stated that a better understanding of the pathologic physiology involved would offer an opportunity for the diagnosis of preclinical pellagra and consequently its better preventive treatment.

NOTICES

REMOVAL

DUNCAN E. REID, M.D., announces the removal of his office from 171 Bay State Road, Boston, to 319 Longwood Avenue, Boston.

BOSTON MEDICAL HISTORY CLUB

There will be a meeting of the Boston Medical History Club at the Boston Medical Library, 8 Fenway, Boston, on Monday evening, February 19, at 8:15. Dr. Robert B. Osgood will talk on "Menders of the Maimed."

All those interested in the subject are cordially invited to attend.

PETER BENT BRIGHAM HOSPITAL

A joint medical and surgical clinic at the Peter Bent Brigham Hospital will be held on Wednesday, February 21, from 2 to 4 p.m. Drs. Marshall N. Fulton and J. Englebert Dunphy will speak on "Itching."

Physicians and students are cordially invited to attend.

THE GUILD OF ST. LUKE

A regular meeting of The Guild of St. Luke will be held at the Hotel Puritan, Boston, on Monday evening, February 19, at 8:30. The members of The Guild of St. Apollonia are invited to attend this meeting. Mr. Constantine E. McGuire, of Washington, D.C., will be the guest speaker, his subject being "Some of the Factors Likely to Affect the Trend of the Fifth Decade of the Century."

BOSTON DOCTORS' SYMPHONY ORCHESTRA

The Boston Doctors' Symphony Orchestra will rehearse under Alexander Theide, former concertmaster with the Cleveland Symphony Orchestra and the Philadelphia Symphony Orchestra, every

Thursday at 8:30 p.m., in Studio A, Station WMEX, 70 Brookline Avenue, Boston. Those interested in becoming members should communicate with Dr. Julius Loman, Pelham Hall Hotel, Brookline (BEA 2430).

UNITED STATES MARINE HOSPITAL

The staff meeting of the United States Marine Hospital, Chelsea, will be held at 'The Hut,' on Friday afternoon, February 23, at 4:00. Dr. Lowrey F. Davenport will talk, his subject being "Suppurative Disease of the Lung."

NEW ENGLAND ROENTGEN RAY SOCIETY

The next meeting of the New England Roentgen Ray Society will be held at the Boston Medical Library on Friday, February 16, at 8:00 p.m.

PROGRAM

Case presentations Drs. W. J. Butler, R. D. Clapp, M. I. Smedal and L. K. Sycamore

Non Medical Uses of Roentgen Rays Dr. W. J. Elliott

Archaeology and Roentgenology Dr. F. T. Hunter

Dinner at the Harvard Club will be served at 6:30 p.m.

NEW ENGLAND SOCIETY OF PHYSICAL MEDICINE

The New England Society of Physical Medicine will hold its next meeting at the Hotel Kenmore, Boston, on Wednesday evening, February 28, at eight o'clock.

NEW ENGLAND HEART ASSOCIATION

The next meeting of the New England Heart Association will be held at the Children's Hospital, Monday, February 26, at 8:15 p.m.

PROGRAM

Follow up Study of Ligated Ductus Arteriosus Cases.

Drs. John P. Hubbard and Robert E. Gross.

Limit of the Normal P-R Interval in Children. Dr. Charles H. Cutler

So-called "Congenital Idiopathic Hypertrophy" Dr. Hyman Green

Paroxysmal Tachycardia and Its Treatment in Young Infants. Dr. John P. Hubbard

Interested physicians and medical students are invited to attend.

NEW ENGLAND HEALTH INSTITUTE

The New England Health Institute, sponsored by the Connecticut State Medical Society, the United States Public Health Service, the United States Children's Bureau, the New England Tuberculosis Association, the state departments of health of Maine, New Hampshire, Vermont, Massachusetts, Rhode Island and Connecticut, the schools of public health of Yale University, Harvard University and Massachusetts Institute of Technology, Simmons College, the Connecticut State Nurses' Association and the Connecticut Public Health Association, will be held at Hotel Bond, 230 Asylum Street, Hartford, Connecticut, on April 15-19, 1940. A preliminary program will soon be available. Those desiring detailed information should apply to the Connecticut State Department of Health, 165 Capitol Avenue, Hartford.

THE FOUNDATION PRIZE

The American Association of Obstetricians, Gynecologists and Abdominal Surgeons announces that the annual Foundation Prize for this year will be \$150. Those

eligible include only interns, residents or graduate students in obstetrics, gynecology and abdominal surgery and physicians who are actively practicing or teaching obstetrics, gynecology or abdominal surgery.

Competing manuscripts must be presented in triplicate under a non-deplume to the secretary of the association before June 1 be limited to 5000 words and such illustrations as are necessary for a clear exposition of the thesis and be typewritten (double spaced) on one side of the sheet, with ample margins.

The successful thesis must be presented at the next annual (September) meeting of the association without expense to the association and in conformity with its regulations.

For further details, address Dr. James R. Blox, Secretary 418 Eleventh Street, Huntington West Virginia.

SOCIETY MEETINGS AND CONFERENCES

CALENDAR OF BOSTON DISTRICT FOR THE WEEK BEGINNING SUNDAY FEBRUARY 18

SENECA F O Y 18

4 p.m. The Medical Care of Domestic Pets. Dr. Gerrit W. Schnelle. Free public lecture. Harvard Medical School, amphitheater of Building D.

4 p.m. Hysteria and Asthma. Dr. Walter S. Burrage. Illustrated, public, health lecture. Fulkner Hospital auditorium.

MONDAY FEBRUARY 19

8:15 p.m. Members of the Maimed. Dr. Robert B. Osgood. Boston Medical History Club. Boston Medical Library.

8:30 p.m. Some of the Factors Likely to Affect the Trend of the Fifth Decade of the Century. M. Constantine E. McGraw. The Guild of St. Luke. Hotel Puritan, Boston.

TUESDAY FEBRUARY 20

9:10 a.m. Paralytic Agitation. Dr. H. I. Harris. Joseph H. Pratt Diagnostic Hospital.

12 m. The Common Diseases of the Veins. Dr. Edward A. Edwards. New England Medical Club. Boston Tuberculosis Association, 554 Columbus Avenue, Boston.

WEDNESDAY FEBRUARY 21

9:10 a.m. Hospital case presentation. Dr. S. J. Thannhauser. Joseph H. Pratt Diagnostic Hospital.

2-4 p.m. Ichthyosis. Drs. Marshall N. Patton and J. Englebert Dunphy. Peter Bent Brigham Hospital.

FRIDAY FEBRUARY 23

9:10 a.m. Epidemiology of Respiratory Infections. Dr. Dwight O'Hara. Joseph H. Pratt Diagnostic Hospital.

SATURDAY FEBRUARY 24

9:10 a.m. Hospital case presentation. Dr. Thannhauser. Joseph H. Pratt Diagnostic Hospital.

Open to the medical profession.

DISTRICT MEDICAL SOCIETIES

ESSEX SOUTH

MARCH 6—Experimental and Clinical Considerations of Sulfanilamide Treatment of Hemolytic Streptococcus Infections. Dr. Champ Lyons. Lynn Hospital, Lynn.

APRIL 3—Addison Gilbert Hospital Gloucester.

MAY 8—Annual meeting. Salem Country Club, Peabody.

FRANKLIN

MARCH 12—Franklin County Hospital, Greenfield.

MAY 14—Franklin County Hospital, Greenfield.

HAMPSHIRE

MARCH 13.

MAY 8.

Meetings are held at 11:30 a.m. at the Cooley Dickinson Hospital, Northampton.

MIDDLESEX EAST

MARCH 20.

MAY 15.

Meetings are held at 12:15 p.m. at the Uxbridge Country Club, Needham.

MIDDLESEX NORTH

MARCH 24.

JUNE 31.

OCTOBER 30.

NORFOLK SOUTH

MARCH 7.

APRIL 4.

MAY 2.

All meetings, with the exception of one which is usually held at the Quincy City Hospital, are held at the Norfolk County Hospital in South Braintree, at 12 o'clock noon.

PLYMOUTH

MARCH 21—Goodland Hospital, Brockton.

APRIL 18—State Farm.

MAY 16—Lakewood Sanatorium, Lakewood.

SUFFOLK

MARCH 27—Scientific meeting. Symposium on Ulcerated Colitis and Dysentery. Under the direction of Dr. Chester M. Jones.

APRIL 24—Annual meeting in conjunction with the Boston Medical Library. Election of officers. Program and speakers to be announced later.

MAY 2—Censors meeting. Page 244 issue of February 8.

WORCESTER

MARCH 13—Worcester Memorial Hospital.

APRIL 10—Worcester Mahernan Hospital.

MAY 8—Worcester Country Club.

Each meeting begins with a dinner at 6:30 p.m. and is followed by business and scientific meeting.

BOOK REVIEWS

Pye's Surgical Handicraft A manual of surgical manipulations, minor surgery, and other matters connected with the work of house surgeons and of surgical dressers Edited by Hamilton Bailey Eleventh edition 512 pp Baltimore Williams & Wilkins Co, 1939 \$6.00

For a book appearing in its eleventh edition, a review is necessary only to increase the number of those who may glean as much nourishment of a practical nature as did the reviewer. Truly valuable, this book is a veritable gold mine of ideas and facts of diagnostic and therapeutic value. As a tribute to its present editor, it is fitting to say that when one reads about a simple, homely, but extremely valuable therapeutic trick one wonders whether it was the brainchild of the original Mr Pye or the equally original but more modern Hamilton Bailey. Mr Bailey discusses "The Treatment of Acute Poisoning" in so simple, yet complete a manner that the entire subject at last resolves itself into common sense. He has added many valuable steps in the care of fractures. His pre-operative and postoperative rules and practices are modern, correct and thoughtful. The book covers general surgery, that of the eye, ear, nose and throat, orthopedics, urology, and the aptly phrased "medical operations." For the urban surgeon, the chapters on hypnotics and sedatives, infections of the hand, sprains, and general and Evipan anesthesia are of interest. There is even a section on tooth extraction. The last eight chapters, barring the excellent treatise on poisons, are apparently planned for the intern but merit perusal. Gynecological problems are discussed sparsely and poorly, as is usually the case except when the author is a full time gynecologist. The long section on laboratory procedures could well have been left to a laboratory manual.

The Health Insurance Doctor His role in Great Britain, Denmark and France Barbara N Armstrong 264 pp Princeton The Princeton University Press, 1939 \$3.00

The authoress is an enthusiastic believer in health insurance and gives "basic information about the situation of the health insurance doctor abroad." With a background of twenty years of research and university teaching in the social-insurance field, she made a personal investigation in 1936 in Great Britain, Denmark and France and gathered facts with the aid and co-operation of both governmental agencies and the medical profession.

Detailed information shows who are insured, how necessary funds are obtained, how doctors are chosen, their duties, how they are paid and what their attitude is toward the plan as a whole.

The British system went into operation in 1912, the Danish in 1892, the French in 1930. In Britain the worker only is insured, in Denmark the worker and his children (the wife is expected to be insured in her own right), in France all members of the family are covered. Insured groups were built up from existing fraternal organizations, with additions and modifications as required to meet new conditions. Insurance funds are made up of contributions by workers, by employers and by the government.

In Britain in 1936 about three fourths of the men and two fifths of the women in general practice were panel doctors. In the Copenhagen area of Denmark over 70 per cent of general practitioners are included, and outside this area nearly all physicians do some insurance work. Everywhere there is freedom of choice of doctors and ample provision for changing from one doctor to another. Hence the insurance doctor, like every other physician, to be successful must have the ability to attract and retain patients.

In Britain and Denmark the doctor is paid quarterly—in Britain from a government pool and in Denmark from the exchequer of health-insurance societies. In Britain payment is on a capitation basis, that is, the number of patients on his medical list at the beginning of the quarter, with additions for certain specified services. In Denmark the capitation basis prevails generally and the tendency is toward making it universal. In France the doctor charges his patients what he chooses and collects what he can. The patient is reimbursed, in part, by his society.

The health-insurance doctor is on a general practitioner basis, with provisions for hospitalization and reference to various specialists in appropriate instances. The fundamental principle is that the traditional, free, doctor-patient relation is desirable, and when economic conditions deny it to workers and their families, health insurance should restore it to them and to the doctors who would like to serve them. "In each country collective action by the organized medical profession plays a vital part in determination of the health insurance doctor's privileges, responsibilities and remuneration."

The doctors believe that health insurance gives a greater professional freedom in practice among the mass of the people, such as is enjoyed in private practice only in treating the well-to-do, also that it gives them a larger and steadier income. "Doctors appreciate security of income as much as anyone!" The regulated aspects, "the price they pay for its advantages, is an inevitable and not very onerous *quid pro quo*." In Britain there is evident a marked change in attitude—from bitter hostility when legislation was being discussed in 1909 and 1910, to enthusiastic approval after years of actual experience. Income

on the wage-earners group is two or three times as great. The pay check comes every quarter, in good times and in bad. Relations with patients are improved. The insured patient can see his doctor whenever he needs to without the barrier of a bill which he could not afford. The doctor can see chronic patients as often as he likes without embarrassment. One doctor gives each new patient a card which reads "If you get a cold come to see me. Let me decide whether it is important. I should like to treat a cold than pneumonia."

Once in Denmark, about twenty years ago because of controversy over the scale of payment, at the end of a year renewal contracts were made and doctors were on private-practitioner terms with insured patients who were entitled to reimbursement by their societies for from 50 to 75 per cent of medical bills which they had paid. This continued for one year but proved unsatisfactory in regard to the relations between doctor and patient and also reduced substantially the doctors' incomes. Since that time the doctors have been more enthusiastic than ever over the benefits of health insurance and more medical services have been included.

Physicians stress the fact that health insurance has greatly improved the practitioner's chance of preventing invalidity of his patients. This applies to loss of time from both acute and chronic disease and especially from tuberculosis.

This book should prove helpful to anyone interested in considering the complex questions of better distribution of medical services—who of us is not interested? Conditions in the United States differ greatly of course, from those in Britain, Denmark and France, but methods which have been tested, adjusted, readjusted, expanded and continued over periods of one to five decades surely are worthy of careful examination.

It is gratifying to note the authoress's recognition of the possibilities and effectiveness of organized medicine in the development and guidance of health insurance.

Winter of Allergy: A guidebook for those who must find their way through the mazes of this strange and tantalizing state. Warren T. Vaughan. 140 pp. St. Louis: The C. V. Mosby Co., 1939. \$1.50

A book, which is to mediate medical problems to the layman is admittedly difficult to write. The obvious dangers are those of either oversimplification leading to inhibition so far as the physician is concerned or of under-simplification leading to incomprehension on the part of the patient. Dr. Vaughan has steered himself a very skillful course. His analogies are so carefully qualified that no allergist could possibly be offended and yet are sufficiently clear to the patient who requires some understanding of the nature of his illness.

The author emphasizes the facts that the causes of allergic reactions are rarely immediate and, hence, that the allusions to the problems presented are not always obvious. This will help with patients who think that the insidious substance should invariably precipitate symptoms with dramatic suddenness. Also of value is the moral exhortation with which the book ends urging the patient to present himself for treatment early in his illness, and to expect full relief only after an adequate time, to be measured sometimes in years.

This little volume will not save the busy physician much of the time he now spends answering the questions of his allergic patients. He can be assured, however, that the questions asked will be much more intelligent, and

that the co-operation desired will be much firmer and long lasting.

Atlas of Surgical Operations. Elliott C. Cutler and Robert Zollinger. 181 pp. New York: The Macmillan Co., 1939. \$3.00

In the preface to this remarkable book the authors point out that while library shelves are filled with excellent systems and textbooks of surgery no manual of the technical steps of the accepted and standardized operations of the day has been offered for almost a hundred years. The volume was modeled after Bernard and Huettes *Précis iconographique de médecine opératoire et d'anatomie chirurgicale* which was published in 1853 and it resembles in many respects Pancoast's *Operative Surgery* published a few years earlier. The steps of some sixty-five common operative procedures ranging from tonsillectomy to abdominoperineal resection of the rectum are illustrated in severe, almost diagrammatic line drawings in eighty-four 10-by-15-inch plates. Opposite each plate is a brief description of the procedure as it is carried out at the Peter Bent Brigham Hospital with an outline of indications and preoperative and postoperative care.

In a few instances the artist, Miss Mildred Coddington has been obliged to sacrifice the illusion of depth for the sake of clarity but where this occurs it is a virtue rather than a fault and the third dimension is easily read into the drawing. Her style of clean-cut line drawing is perfectly suited to the subject matter and it is to be hoped that its successful employment in this book will mark the end of the fuzzy half tones so often seen in surgical literature.

Almost every surgeon of experience will disagree with certain of the procedures described. For example, one may favor a transverse rather than a vertical incision for simple mastectomy or be inclined to employ the closed Parker-Kerr type of intestinal anastomosis on the large bowel rather than the open method. But these are minor details and all will agree that the operations as outlined are safe and satisfactory procedures for the young surgeon, to whom the book is dedicated.

It is to be hoped that future editions will include descriptions of the common and standardized operations on fractures, such as suture of the olecranon and the patella. Also, presentation of certain more or less emergency procedures, such as the ligation of a bleeding middle meningeal artery or suprapubic cystostomy would be welcomed particularly by those who practice in rural regions.

This book will undoubtedly and deservedly become very popular. It should be in the library of every hospital in which young men are trained in surgery and there is no volume which could better serve as a *vade mecum* in technique for the practicing surgeon.

Cancer of the Colon and Rectum: Its diagnosis and treatment. Fred W. Rankin and A. Stephens Graham. 358 pp. Springfield, Illinois, and Baltimore: Charles C. Thomas, 1939. \$5.50.

In estimating the worth of a book one is rightly influenced by the reputation and previous experience of its author or authors. Few if any contemporary surgeons in this country have had greater opportunities to study and treat cancer of the large bowel than Rankin, who with the able assistance of Graham, records in this book the results of his extensive work at the Mayo Clinic and more recently in Lexington, Kentucky.

The volume is divided into three parts of five chap-

ters each, dealing with general considerations, treatment and operative procedures, respectively. The anatomy and physiology of the colon and rectum are ably discussed, with particular reference to the practical considerations hinging thereon. An adequate bibliography backs up the theories and figures relating to incidence, occurrence and etiology. The role of benign adenomas and multiple familial polyposis as precancerous lesions is rightly stressed.

One chapter devoted to differential diagnosis provides opportunity for a brief but complete statement of the proper methods of treatment of those other lesions of the colon and rectum with which cancer may be, and often is, confused.

In the second part, operability and prognosis, together with the many factors influencing their statistics, are discussed and supplemented by previously published tables of Rankin and his associates and of Gabriel and by those of the St. Marks Hospital, London.

In regard to choice of operation emphasis is paid properly on the point that any procedure, though it may vary in technical details, must be sufficiently thorough in scope of removal if it is to be considered a proper cancer operation.

Numerous tables having to do with mortality and end results are included from the writings of most of the best surgeons in this field, including those of the late Daniel F. Jones, whose experience with cancer of the large bowel was second to none.

The last 100 pages are devoted to detailed descriptions of all the operative procedures in common use and to line drawings which clearly illustrate these operations.

It is not an exaggeration to say that no other single book in the English language gives so complete and reliable an account of the diagnosis and treatment of cancer of the large intestine.

Radiologie Clinique du Coeur et des Gros Vaisseaux
C. Laubry, P. Cottenot, D. Routier, and R. Heim de Balsac. 2 vol., totaling 340 pp. Paris: Masson et Cie, 1939. 430 Fr. fr.

Following the fine tradition of the French school in cardiovascular roentgenology represented less than a generation ago by Bordet and Vaquez, Professor Laubry and his colleagues Cottenot, Routier and Heim de Balsac of the Faculty of Medicine of Paris and Hôpital Broussais-La Charité, have published, with the collaboration of Masson et Cie, two volumes of excellent x-ray pictures and diagrams illustrating normal and abnormal variations of size and shape of the heart and great vessels. As the authors write in the very first sentence of the introduction, this work represents the synthesis of their efforts of more than ten years. It is an account in large part of personal experience, thereby giving it greater value, but at the same time there is appended a useful bibliography of several hundred authors of all nationalities. The volumes form an instructive atlas for teaching purposes and immediate practical use; they are not intended as a routine textbook or complete treatise on the subject of cardiac roentgenology. All who peruse this work will at once appreciate its utility.

The first volume contains Part I, "General Observations," Part 2, "The Normal Heart," and the first chapter of Part 3, "The Pathologic Heart." The second volume contains the rest of Part 3, that is, the remaining six chapters on the pathologic heart.

Under general observations are presented the usefulness of x-ray examination of the heart and great vessels, the

methods of examination (radioscopy, orthodiagraphy, teloradiography, cineradiography, radiokymography, opacification of the heart and vessels, radiodensitometry, and tomography and seriescopy) and details of the techniques of radiography, radiokymography and cardiovascular angiography.

The second part on the normal heart presents morphology (factors which determine 'interindividual differences' and morphologic modifications in the same individuals), radiological anatomy in the frontal, right anterior oblique, left anterior oblique and left transverse positions, the value and interpretation of measurements, radiokymograms and particular features of certain cardiovascular silhouettes.

The third and last part is naturally the most extensive, presenting in Chapter I a wealth of illustrative material on rheumatic heart disease, with especial reference to the effect of the various valvular lesions, single and combined. Chapter II discusses congenital defects (interventricular septal defect, pulmonary stenosis, aortic stenosis, coarctation of the aorta, patency of the ductus arteriosus, interauricular septal defect, valvular deformities of the left heart, right aortic arch, situs inversus and "idiopathic" cardiac hypertrophy of the infant). Chapter III concerns the so-called "arterial cardiopathies" (aortitis, aortic aneurysms, "chronic diffuse myocarditis," partial aneurysms of the heart, pulmonary arterial aneurysms and non-aneurysmal dilatations, and arterial hypertension). Chapter IV presents pericardial abnormalities (effusions, adhesions and diverticula). Chapter V gives a few illustrations of cardiac hypertrophy, dilatation and failure, involving the left or right ventricle or both. Chapter VI devotes a few pages to intracardiac and mediastinal foreign bodies. Finally, Chapter VII presents thoracic pictures difficult to interpret—an interesting though limited collection of films. Following the bibliography already referred to there is an adequate alphabetical subject index.

The reviewer wishes there were more complete illustration of various conditions,—in particular the dilated heart of early rheumatic infection in childhood before valvular disease has developed, the cor pulmonale, the hypertensive heart and certain other rarer conditions,—but for the time being we must be content with the limited but excellent material presented. Perhaps in a later edition another volume could be added or the present ones made somewhat larger to fill these gaps, for it would be well worth while. This work, as it is, can be heartily recommended to students and physicians who are interested in x-ray pictures of the heart and great vessels, which should include all who practice internal medicine. The expense of the volumes may prevent their wide dissemination through the profession at large but they should at least be in all medical libraries which are consulted by students and practitioners. The fact that the text is in French should not be a drawback because of the wealth of illustrations and the ease with which the main headings of the legends can be translated.

The Hospital Care of Neurosurgical Patients Wallace B. Hamby. 118 pp. Springfield, Illinois, and Baltimore: Charles C. Thomas, 1940. \$2.00.

With the growth of neurological surgery in the last fifteen years, there has come new responsibility in caring for these patients from the point of view of nursing. Both preoperative and postoperative care offer problems which do not ordinarily arise in connection with patients undergoing general surgical treatment. Dr. Hamby has visualized these problems and has written a brief book which ought to be of distinct value to nurses and junior physicians.

SUBPHRENIC ABSCESS*

A Report of One Hundred and Eleven Consecutive Operative Cases

HENRY H. FAXON, M.D.†

BOSTON

THE most satisfactory method of handling an inflammatory process beneath the diaphragm is still a matter of debate, and any clarification of the disputed issues must come as a result of study of a number of cases sufficiently large to be of significance. During the years from 1900 to 1938, inclusive, there have been 175 cases at the Massachusetts General Hospital in which a diagnosis of a subphrenic infectious process has been made (Table 1). In 22 cases, undrained abscesses,

and those with true subphrenic abscess for matation.

Six patients, on whom operation was performed but without encountering pus, were presumably suffering from a similar nonsuppurative type of lesion. Thus, in 38 or 22 per cent of the cases there was an inflammatory process beneath the diaphragm for which no surgical intervention was indicated. Undoubtedly there were an indeterminate number of cases falling into this same category that were never recorded as subdiaphragmatic inflammation because of the surgeon's unwillingness to make a diagnosis which could not be confirmed. Lee² points out in reporting a selected number of these same cases that the occurrence of subphrenic inflammation subsiding without operation is not a rare finding. Ochsner and Graves³ state that over two thirds of all subphrenic infections subside without suppuration, and I suspect that their estimate more nearly approaches the true incidence of this condition than does the 22 per cent given above in connection with the present series.

ANATOMY

Martinet⁴ in France and Barnard⁵ in England, at the beginning of this century first accurately described the subphrenic spaces, and since that time it has generally come to be accepted that the term "subphrenic" as used to designate the localization of an abscess refers not alone to the region immediately below the diaphragm, but includes as well an area that extends as far down as the transverse colon. If this more comprehensive space be considered it will be seen that it is subdivided by the ligaments of the liver and the adjacent structures. To the right of the falciform suspensory ligament, and bounded by the liver edge below, lie the right anterior and right postero-

TABLE 1 Cases Diagnosed as Subphrenic Abscess or Subphrenic Inflammation

| CLASSIFICATION OF CASE | NO. OF CASES |
|--|--------------|
| Operation for subphrenic drainage | 111 |
| No operation ("subphrenic inflammation") | 32 |
| No operation for subdiaphragmatic abscess (confirmed at autopsy) | 22 |
| Operation but no pus encountered | 6 |
| Spontaneously drained via previous operative sinus | 4 |
| Total | 175 |

usually of secondary importance to other equally lethal diseases, were discovered at autopsy. A study of the clinical course in these cases, however, gives added weight to the findings of Ochsner and DeBakey¹ in a large series of cases assembled from the literature. These demonstrated that collections of pus beneath the diaphragm will terminate in a fatal outcome in approximately 90 per cent of cases unless they are surgically drained.

Spontaneous drainage was encountered in 4 cases of this series, in all of which the apparently bealed sinus, formed about the wick of a previous laparotomy, served as a guide for the escape of pus imprisoned beneath the diaphragm.

In 32 cases the clinical course, physical findings and x-ray evidence suggested a mild irritative process beneath the diaphragm. All these patients recovered without surgical interference, and a diag-

*Read at the annual meeting of the New England Surgical Society, Salem, Massachusetts, September 29, 1939.

†Assistant in Surgery, Harvard Medical School; senior surgeon, Massachusetts General Hospital, Boston.

superior spaces, separated by the cardinal ligament of the liver and its lateral extension (Figs 1 and 2). The anterior space is by far the larger of the two because of the decidedly posterior position of this ligament. Between the leaves of the ligament and abutting on the peritoneal cavity, but not actually within it, is a distinct and separate area which is extraperitoneal, and may represent the confines

again three spaces, but because of the extreme posterior position of the left lateral ligament there is but a single superior space. The left postero-inferior space is the lesser peritoneal cavity, while the left anterior space is bounded by the liver above, the stomach below and the gastrohepatic omentum posteriorly.

It is a lack of familiarity with these constant anatomic spaces that often leads to an unwise selection of approach for drainage, and to an unfortunate hesitancy in the actual execution of the operation. That a certain amount of ambiguity exists in the minds of some surgeons regarding these spaces is not surprising, because of the relative infrequency with which any one surgeon is called on to differentiate them. In this series, the greatest number of cases drained by any individual was only 10, and fifty-two different operators were responsible for the surgical treatment of the 111 cases reported.

AGE INCIDENCE AND SEX DISTRIBUTION

The age incidence in the 111 operative cases of subphrenic abscess showed a steady increase from the first to the fifth decade, the average age for the group as a whole being thirty-eight years (Table 2). The youngest patient was three years

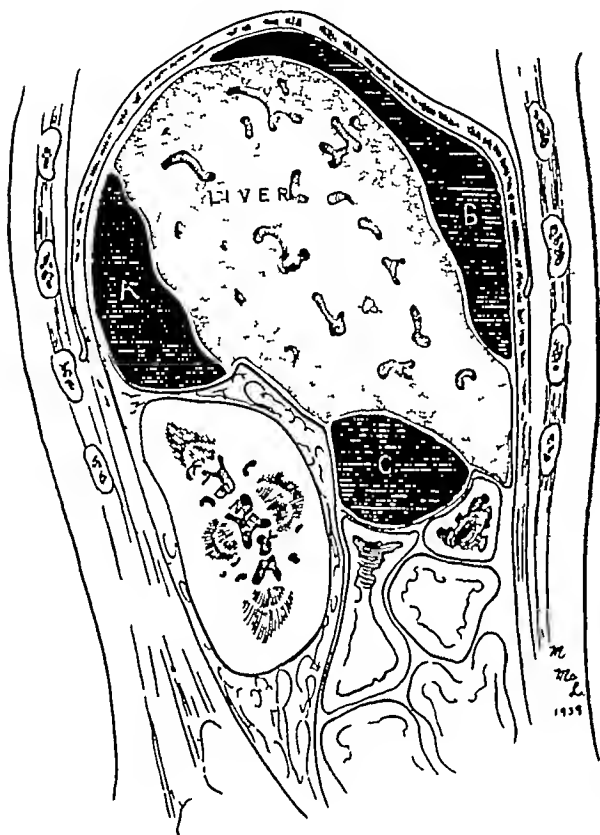

FIGURE 1 *Sagittal View of the Right Abdomen*

of a subphrenic abscess or the extension of a process from one of the adjacent spaces. The right inferior space is bounded by the kidney posteriorly, the undersurface of the liver above, the round ligament and the ligament of the ductus venosus medially, and the transverse colon below. In addition to these divisions on the right, a potential retroperitoneal space exists between the diaphragm and the diaphragmatic peritoneum that may become distended with pus from a dissecting retroperitoneal infection. In this series the latter space played a relatively minor role.

The left subphrenic area is far less commonly involved than is the right, there being only 13 per cent of this series in which an abscess was found to the left of the midline. On this side there are

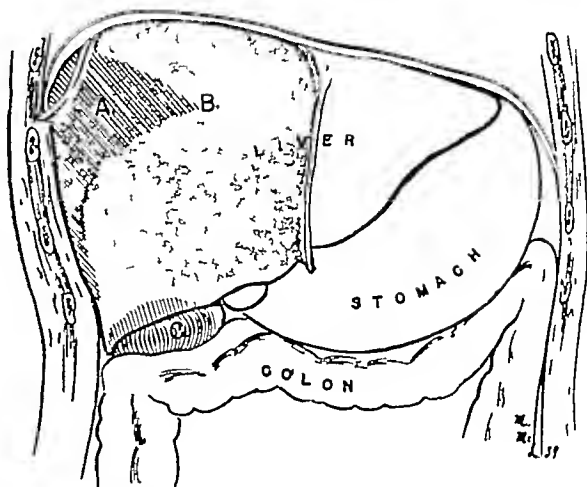

FIGURE 2 *Anterior View of the Abdomen*

This shows the relative sites of abscesses occurring in the three most commonly involved subphrenic spaces. A—right posterosuperior, B—right anterosuperior, C—right inferior. The shaded portions of A and C are actually not visible in this view as they lie behind the substance of the liver.

old and the oldest was seventy-six. As regards the distribution of the sexes, 68 of the patients (61 per cent) were men.

ETIOLOGY

Although certain subphrenic infections undoubtedly gain access to the subdiaphragmatic area by way of the lymphatics and the blood stream, the

vast majority originate from an extension of in traperitoneal sepsis. Such extension up the lateral gutter is favored by the presence in the upper abdomen of a negative pressure fluctuating with respiration, as demonstrated by Overholt.⁶ In addition to this factor, the ventral curvature of the lumbar spine with the patient in the supine position

TABLE 2. Incidence according to Decades

| Age | No. of Cases | Per Cent of Total Cases |
|-------------|--------------|-------------------------|
| 31 | 6 | 5 |
| 10-20 | 12 | 11 |
| 20-30 | 15 | 13 |
| 30-40 | 25 | 23 |
| 40-50 | 23 | 21 |
| 50-60 | 23 | 21 |
| 60 and over | 7 | 6 |
| Total | 111 | |

tion results in a transverse ridge that favors the gravitation of pus distally into the pelvis and proximally into the subdiaphragmatic region.

Infection originating in the appendix, as shown in Figure 3, is the commonest source of subphrenic

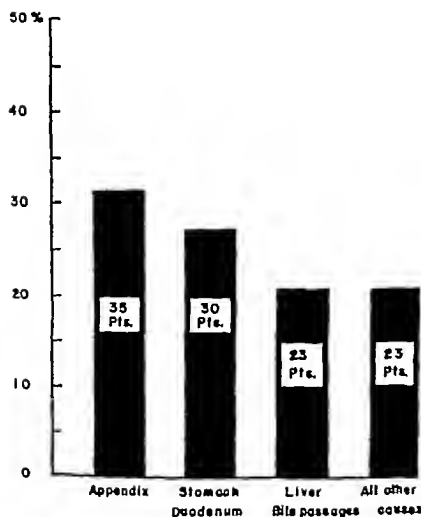

FIGURE 3. Etiology of Subphrenic Abscess

abscess formation, and was responsible for 31 per cent of the cases in this series.

Second in importance as the primary source of infection were lesions in the stomach and duodenum, responsible for 27 per cent of the abscesses, while those in the liver and bile passages, with 21 per cent, ranked third. All other sources com-

bined (21 per cent) individually played very minor roles as etiologic factors. In the collected series of cases reported by Ochsner and DeBakey,¹ and already referred to, the order of importance in the inciting causes was found to be the same.

DIAGNOSIS

The presence of a subphrenic abscess should be suspected in any patient with a persistent unexplained fever associated with a history of recent intraperitoneal sepsis. It should be borne in mind that not infrequently (in 26 per cent of these cases) the inciting cause is never clearly established, although in most cases in this series (64 per cent) an antecedent laparotomy had either confirmed the presence of a septic focus, or had itself proved to be a source of untoward peritoneal contamination. Ten per cent of the patients had had no operation preceding the drainage of their abscesses, but because of the accurate histories there was little doubt as to the original source of infection.

In its early stages it is not always easy to diagnose the condition. Not only may there be some doubt as to whether the infection about the diaphragm is above or below that structure, but the decisions as to whether the infection will subside

TABLE 3. X Ray Data in 83 Cases* of Subphrenic Abscess

| X Ray Data | No. of Cases | Percentage of Total Cases |
|--|--------------|---------------------------|
| Diaphragm elevated | 65 | 78 |
| Diaphragm not elevated | 3 | 4 |
| Diaphragm not visualized | 15 | 18 |
| Fluid level and gas below diaphragm | 221 | 26 |
| Opaque injection into pre-existing sinus | 5 | 6 |

*In 28 cases no preoperative x-ray films were taken. None of these cases showed no fluid level, although gas could be demonstrated.

without suppuration and as to which of the spaces it involves are both of prime practical importance. Granted the case in which it is reasonable to suspect the presence of a subphrenic abscess, the diagnosis is made on one or more of the following points: the presence of tenderness over the twelfth rib or lower costal margin to firm palpation or compression, the clinical findings of a high, fixed diaphragm on the affected side, together with such manifestations of diaphragmatic irritation as pain referred to the shoulder or neck, hiccoughs and discomfort on deep respiration, and the confirmation by roentgenological studies of the clinical impression as to the position and excursion of the diaphragm.

Table 3 gives the x-ray findings in the 83 cases so studied, and substantiates the statement of LeWald⁷ that, regardless of the space involved, the

diaphragm if it can be visualized by x-ray will almost invariably be found to be elevated and usually fixed. The presence of gas and a fluid level occurred in 26 per cent of our cases, either as a late finding, or because of the introduction of gas into the involved area from a perforated viscus or an externally draining sinus. It should be remembered that following laparotomy alone, free air beneath the diaphragm may be demonstrated frequently by x-ray for as long as two weeks after operation, as brought out by Muller, Overholt and Pendergrass.⁸ Those cases in this series in which no x-ray films were taken were largely the ones dating back to the earlier period when such studies were not readily available. In 5 of the cases, the

to attempt to secure a satisfactory lateral plate or to carry out fluoroscopic studies, but whenever the patient's condition will permit these procedures, the evidence so secured will be of inestimable help in establishing which of the subdivisions is involved.

The presence of serous effusion above the diaphragm is another suggestive sign of the existence of a subphrenic abscess, although opinions differ as to the constancy of this finding. Thus, Clute⁹ and Beyer¹⁰ believe that it is almost invariably present, whereas Ochsner¹³ contends that it is usually a late finding in neglected cases. In attempting to arrive at a conclusion on this point from the findings in this series (Table 4), it seemed unwise

FIGURE 4 Lateral X-Ray Film of an Abscess Cavity

This lies in the right posterosuperior space and has been injected with Lipiodol through a persistent sinus following cholecystectomy with drainage. There is some distortion due to the angle at which the exposure was made. The involved area has been retouched for greater clarity in the reproduction. The patient promptly recovered following drainage by the retroperitoneal type of approach.

injection of a radio-opaque substance into a sinus tract, persisting from previous operative drainage, served as a simple method of demonstrating the location of a residual subphrenic abscess (Fig 4).

It is obvious from a review of the more recent records that in many cases the surgeon did not fully avail himself of the help that x-ray studies might have afforded, but was satisfied with a simple anteroposterior view and a statement that the diaphragm was elevated and fixed. There are, of course, patients so ill that it may seem unwise

TABLE 4 Findings as Regards Pleural Effusion Associated with Subphrenic Abscess

| CLINICAL DATA | NO OF CASES | PERCENTAGE OF TOTAL CASES |
|--|-------------|---------------------------|
| No chest tap or operative comment on visualization of pleural cavity | 73 | 66 |
| Empyema at time of subphrenic drainage | 9* | 8 |
| No fluid by chest tap (4) or by visualization (5) | 9 | 8 |
| Pleural effusion by chest tap (20) or visualization (0) | 20† | 18 |
| Total | 111 | |

*78 per cent of these were grossly neglected cases occurring prior to 1924.

†85 per cent of these involved one of the superior spaces.

to hazard a definite statement as to the presence or absence of chest fluid in the 73 cases in which neither a chest tap nor direct visualization of the pleural cavity had been carried out. In 9 neglected cases, all but 2 of which occurred prior to 1924, a definite diagnosis of empyema had been established at the time of the subphrenic drainage. Thus, there remained 29 patients with subphrenic abscesses confirmed by operation whose pleural cavities were either explored by thoracentesis (24 cases) or by visualization at the first stage of the transpleural technic of subdiaphragmatic drainage (5 cases). Judged by such criteria, 8 per cent of the total number of cases showed no fluid, whereas 18 per cent showed it to be present in varying amounts.

It might be assumed that the longer the subphrenic abscess has been present without adequate drainage, the greater would be the incidence of pleural effusion. I fully realize that it is impossible to draw any final conclusions from these figures, but the fact that the average elapsed time between the onset of the original septic process and the exploration of the pleural cavity was thirty days in the cases in which no fluid was demonstrated, and twenty-six days in the ones in which an effusion was found, suggests that the duration of the subphrenic abscess is not the sole factor in

determining the incidence of pleural involvement

The fact that 85 per cent of those cases in which the presence of fluid above the diaphragm was established had a subphrenic process involving one of the superior spaces, bears out the assumption that the abscess must almost always be in direct contact with the diaphragm in order to give pleural effusion above it

Downward displacement of the liver is often

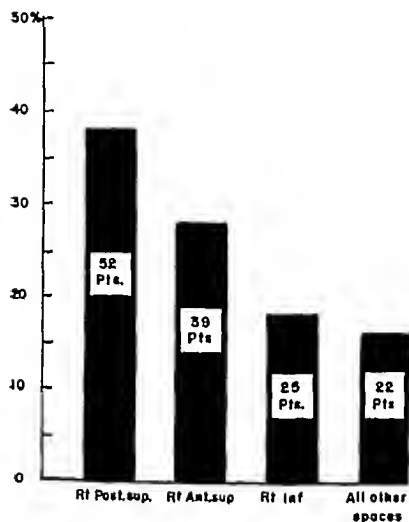

FIGURE 5 Localization of Subphrenic Abscess

A total of 138 spaces were involved in the 111 cases. The "all other spaces" included left superior 8 per cent, left antero-inferior 5 per cent and retroperitoneal 3 per cent.

difficult to determine, but if this finding can be established it is an added factor suggestive of an abscess in one of the superior spaces

the time of the antecedent laparotomy and the institution of drainage for the subphrenic abscess, when both of these were carried out at the same hospital entry. It might well be expected, and is certainly to be hoped, that in future, with more intelligent interpretation of the x-ray data and less reticence in accepting suggestive findings as an indication for surgery, operation will be instituted earlier. I am sure that an occasional negative exploration early in the period when a subphrenic abscess is suspected is far more desirable than procrastination carried to a degree that renders the presence and location of the abscess self-evident.

LOCALIZATION OF ABSCESS

In 87 per cent of the cases the abscesses were on the right side (Fig 5), with the right postero-superior space most frequently involved (38 per cent), and the right anterior (28 per cent) and the right inferior (18 per cent) spaces of lesser importance, 3 per cent of the abscesses on the right side were in the retroperitoneal areas. The necessity of determining before operation which space or combination of spaces is involved cannot be overemphasized, this determination can best be made by an observance of the following factors:

The location of the point of maximum tenderness. It is at times difficult to elicit convincing evidence from pressure over the twelfth rib posteriorly or the lower costal margin anteriorly in the early stages of development of an abscess. However, repeated examinations will eventually show tenderness to be present over an involved space in practically every case. Not infrequently deep pressure or compression of the lower chest wall will elicit this sign when it cannot be demonstrated by lighter forms of palpation.

The x-ray findings especially those shown by fluoroscopy and lateral films, and those taken after

* A total of 138 spaces were involved in the 111 cases.

It is disappointing to note that, as time has gone on, there has been no appreciable decrease in the average interval of twenty six days between

the injection of a radio-opaque substance into a pre-existing inadequately draining sinus tract.

A consideration of the original septic process

with special reference to the most likely site of its extension beneath the diaphragm (Table 5) Thus, in the 35 cases in which an acute appendix was the causative factor, 68 per cent of the associated subphrenic abscesses were found in either the right posterosuperior or right inferior space. It is of interest to note that nearly half the abscesses following surgery on the gall bladder occurred not in the dependent right inferior space, which presumably was adequately drained at the time of operation, but in the contaminated but undrained right anterosuperior space. When the stomach or duodenum, either from perforation or previous surgery, was the source of the original infection, the right anterosuperior space was involved in 39 per cent of the subsequent subphrenic abscesses, and the right posterosuperior space in 29 per cent. More than one of the spaces was involved in 24 cases, the commonest combination of the right posterosuperior and right inferior spaces being found in 13 per cent of the series.

The *aspiration of pus from a suspected area* beneath the diaphragm. This adjunct to localization is mentioned here because of the frequency with which it is employed rather than because of any inherent merit in the procedure. Personally, I agree with Whipple,¹¹ Schwartz¹² and numerous others that it is a pernicious practice that should be condemned, because of the risk attendant on the removing of a contaminated needle through an uninvolved serous cavity. Although a productive tap is indisputable evidence of the presence of pus, failure to locate pus with a needle cannot be taken as evidence that no abscess exists, and the contention that because of the septic process beneath the diaphragm the lower portion of the pleural cavity will have become shut off by adhesions, making thoracentesis a perfectly safe procedure, cannot be relied on. The only time when I believe aspiration is justified is at operation after the preliminary steps have been taken so that the surgeon by direct visualization can satisfy himself that there is no possibility of contaminating an uninvolved area. Even under such circumstances an incision to permit a more generous exploration beneath the diaphragm would usually seem more desirable than the blind searching of the region with a needle. Attempts to locate the abscess by aspiration before operation are recorded in 13 cases, while an exploratory needle was used at the time of operation in 28.

Thoracentesis of the pleural cavity to determine the presence and nature of fluid in this space may be carried out to advantage in certain cases of suspected subphrenic abscesses in order to differentiate an empyema and a sterile collection of transudate above the diaphragm. However in such exploratory preoperative aspirations care should be

taken that the tip of the needle does not pass beyond the confines of the pleural cavity.

TREATMENT

Granted the diagnosis of a collection of pus beneath the diaphragm, there is complete unanimity of opinion that the treatment lies in prompt drainage of the area. It is not within the province of this paper to give a detailed description of the various technics that may be employed, for any surgeon interested in the subject is already familiar with the transthoracic methods and the retroperitoneal types of approach. The moot question, however, of the choice between these two broad classifications of drainage is most pertinent. All surgeons would be in accord in favoring that procedure which will most promptly and effectively drain the abscess with the smallest risk to the patient. The final decision should be based on a consideration of fundamental surgical principles and a study of the reports contrasting the two methods of approach.

The advocates of the transthoracic approach argue that it is superior because it affords more direct access to the involved area. I believe, however, that they discount too readily the increased risk of contamination of the pleural cavity inherent in this type of drainage. The contention that such contamination will rarely occur seems to be controverted by the fact that soiling of the pleural cavity took place in 32 per cent of the cases so drained, the percentage being slightly higher if only the cases done in two stages be considered. The delay that a two-stage procedure necessitates is a further but less important consideration that is often overlooked.

It should be pointed out that in only 13 of the 42 cases drained by the transthoracic approach was the procedure done in two stages, for most of the earlier cases were done at a single operation. At the present time, few surgeons would defend the one-stage procedure save in exceptional cases, for it cannot be assumed that the pleural cavity at the costophrenic angle will have become obliterated because of the infectious process below the diaphragm. It is apparent from a study of the relatively small segregated group of cases done in two stages that the results are distinctly more favorable than would appear from the figures of this transpleural group as a whole.

The advocates of the retroperitoneal type of approach, so well described and illustrated by Ochsner and Graves,³ contend that this method at a single operative step gives the abscess adequate dependent drainage with the smallest chance of contaminating uninvolved surfaces. In only 4 per cent of our cases in which this method was employed was either the pleural or peritoneal cavity

inadvertently opened and contaminated. The average postoperative stay in the surviving cases since 1917, when our convalescent home was abandoned, was forty-three days for the cases drained retroperitoneally, and fifty-eight days for those drained by the thoracic approach. Such a protracted convalescence, regardless of the type of operation employed, should not be necessary with prompt diagnosis and earlier institution of drainage.

In the cases in which the right posterosuperior or right inferior space was involved, the operative technic consisted of resection of the entire twelfth rib and division of the underlying fibers of the diaphragm and fascia in order to permit access to

ately placed below the costal margin of the area in which tenderness could be elicited. Thus, in the right anterior space it was made obliquely below the ribs anteriorly and extended down to, but not through, the peritoneum. By blunt dissection, chiefly with the finger, the peritoneum was then separated from the overlying layers until the abscess cavity was reached and could be broken into without contamination of the general peritoneal cavity. The retroperitoneal type of drainage was employed in 49 cases.

There is no justifiable defense for the transperitoneal approach in the drainage of the superior subphrenic spaces, as it has no valid advantage over the other methods, and implies contamination of the peritoneal cavity. It is true that with the less commonly involved left inferior space this type of approach must necessarily be used. However, the formation of adhesions between the anterior abdominal wall and the underlying abscess in this group of cases usually renders the operation under these circumstances extraperitoneal, in the sense that there is no further contamination of the general peritoneal cavity. In the great bulk of the 20 cases done by the transperitoneal approach, this was carried out in the early years of the series, before the advantages of the retroperitoneal type of operation were fully appreciated.

MORTALITY RATE

It is hard to arrive at a fair criterion for determining the mortality rate attributable to subphrenic abscesses, because of the difficulty in evaluating the importance of the original focus of infection as a factor in a fatal outcome. Certainly many of these cases, even if they had never developed a subdiaphragmatic process, had ample cause for death, but to attempt to segregate the cases in which the fatality was due to the primary lesion from those in which the subphrenic abscess could be held responsible would introduce so large a variable human factor as to make the figures meaningless. For this reason, all the deaths in this series are included in computing the mortality rate of 37 per cent for the 111 cases as a whole.

Complications attributable to the fact that the subphrenic process arose prior to drainage or as a result of it contributed toward increasing the number of deaths. Delay in diagnosis was responsible in practically every case for the more serious complications present before operation. The occurrence, relatively early in the series, of 6 cases of rupture of the diaphragm, 3 of these resulting in bronchopleural fistulas, and of an additional 3 cases of pre-existing empyema brings out the dangers of procrastination.

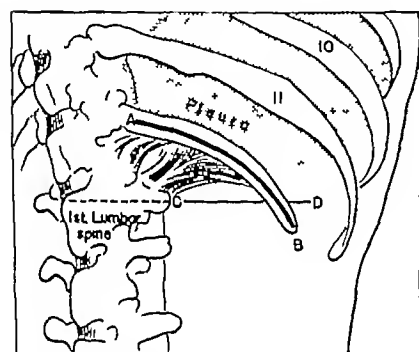

FIGURE 6. Diagrammatic Sketch

This shows the proper line of division of the fascia (C-D) at the level of the first lumbar vertebra. Such an incision invariably avoids contamination of the pleural cavity which would occur in certain cases if the dissection were carried down beneath the line of the skin incision (A-B) and through the bed of the twelfth rib.

the retroperitoneal space. From this point, the abscess cavity could be reached by blunt dissection of the peritoneum and entered directly. In dividing the fascia, care should be taken to make the incision horizontally at a level of the first lumbar spinous process rather than obliquely along the bed of the twelfth rib (Fig 6), as failure to observe this precaution will result in a disastrous contamination of the pleural cavity in a certain number of cases. This has been shown to be possible by Melnikoff¹³ in a study of cadavers in which he demonstrated that the pleura on the right extends to below the twelfth rib in 62 per cent of all cases, but is never found as low as the level of the first lumbar spinous process.

In the retroperitoneal approach to the other subdiaphragmatic spaces, the incision was appropri-

That contamination of the pleural or peritoneal cavity at the time of operation will result in rais-

TABLE 6 *Effect of Contamination at Time of Operation on the Mortality Rate*

| LOCATION OF CONTAMINATION | No OF CASES | MORTALITY % |
|---|-------------|-------------|
| Both pleural and peritoneal cavities contaminated | 1 | 100 |
| Pleural cavity contaminated | 16 | 69 |
| Peritoneal cavity contaminated | 17 | 53 |
| Neither cavity contaminated | 77 | 23 |
| Total | 111 | |
| Grand average | | 37 |

ing the mortality rate should be self-evident, and Table 6 bears out most strikingly the truth of this statement, for it will be seen that with soiling

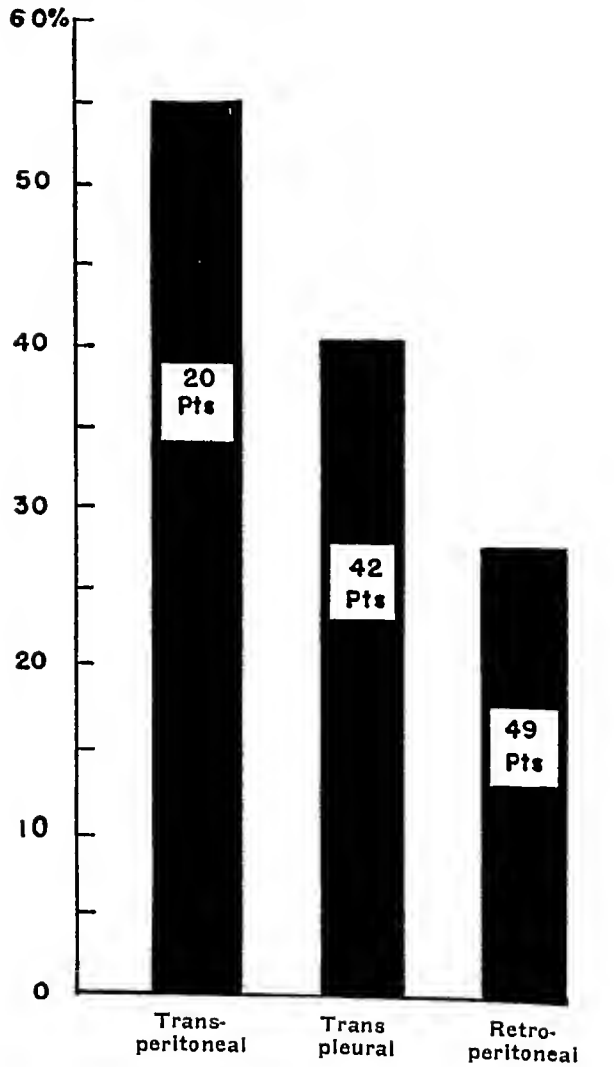

FIGURE 7 *Mortality Rate According to the Type of Operation*

of either of these cavities there is well over a two-fold increase in the mortality figure. That there is a wide variation in the risk of such contamination with the different types of operation has already been referred to, and I believe that it is

this factor which accounts for a difference in the mortality figures (Fig 7) of 55 per cent for the transperitoneal approach, 41 per cent for the transpleural type of drainage and 27 per cent for the retroperitoneal operation. In the series of collected and personal cases reported by Ochsner,¹ the same relation existed and was even more striking, for

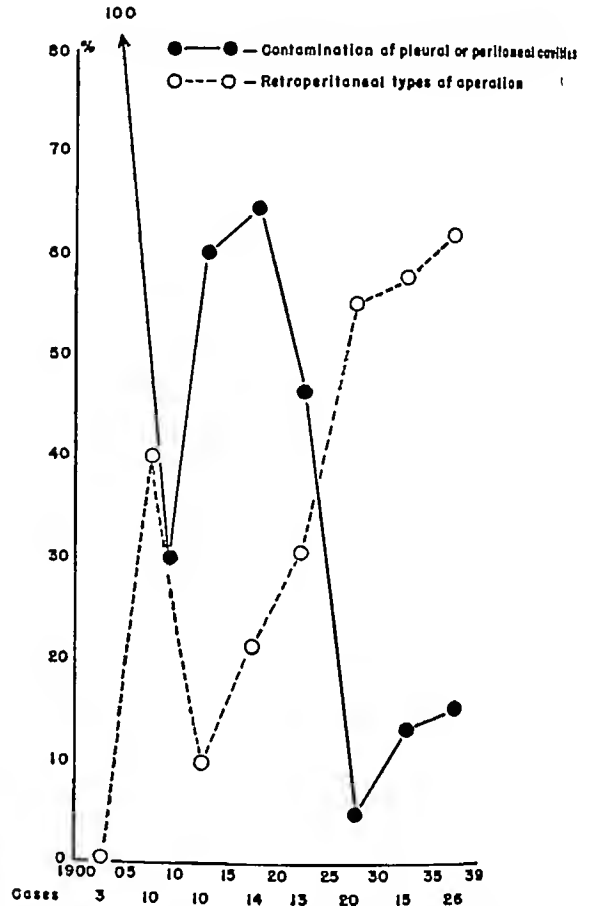

FIGURE 8 *The Percentage Contamination of the Pleural or Peritoneal Cavity and the Incidence of the Retroperitoneal Types of Operation, According to Five Year Periods*

in those cases the mortality rate in the patients drained by the retroperitoneal method was only slightly more than half that found with either the transpleural or the transperitoneal approach.

A growing conviction that the extraperitoneal approach is the safest type of operation accounts for our increasing use of this procedure (Fig 8), and from a study of the cases it appears valid to conclude that the consequent proportionate decrease in the number of cases of contamination of the pleural and peritoneal cavities was due almost wholly to the wider adoption of the retroperitoneal operation. If Figure 8 be studied in conjunction with Figure 9, it will be seen that almost without exception the mortality rate has varied proportionately with the incidence in the use of the retroperitoneal type of operation.

It might seem from the above and from the published reports of others¹⁻³ that there would no longer be any sustained effort to defend the transpleural method of approach, yet in numerous recent cases I have found ardent champions of this apparently less desirable type of operation

SUMMARY AND CONCLUSIONS

The statistical data relative to the 111 consecutive, drained cases of subphrenic abscess occurring at the Massachusetts General Hospital from 1900

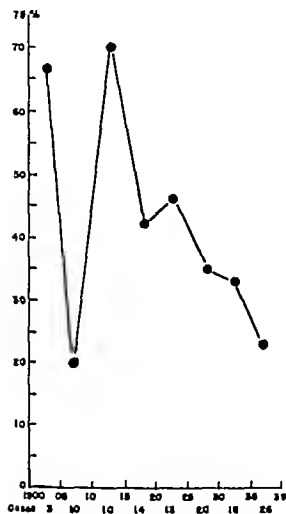

FIGURE 9 The Mortality Rates According to Five Year Periods

to 1939 are presented. The importance of early and accurately localized diagnosis of the involved area is stressed. The advantages of the retroperitoneal over other surgical types of drainage are emphasized.

From these data it can be concluded

At least one fifth of all infections in the subphrenic region subside without abscess formation.

The proper treatment of a subphrenic abscess is prompt surgical drainage.

A diagnosis of an abscess beneath the diaphragm that does not differentiate between which of the clearly demarcated subphrenic spaces is involved leads to hesitancy in the method and time of operation.

The right side is involved nearly seven times

as frequently as the left, with the right posterior and anterosuperior spaces the site of the abscess in two thirds of all cases.

Contamination of the pleural or peritoneal cavities at the time of operation more than doubles the mortality rate.

Contamination of the pleural or peritoneal cavities occurs far more frequently with the transthoracic and transperitoneal types of approach than it does with the retroperitoneal operation.

Both the theoretical and the statistical evidence favor the retroperitoneal type of operation as the procedure of choice in the drainage of a subphrenic abscess.

DISCUSSION

DR. HOWARD M. CLUTE, Boston: In the consideration of subphrenic abscess, the first requirement, as Dr Faxon has clearly pointed out, is the early recognition of the condition. He has shown very clearly that the patients who had had the disease for a long time were poor risks and had a poor chance of recovery.

In our hospital when a postoperative case develops a fever we expect that in the majority of cases, if we are careful enough and hunt hard enough, we shall find that the cause is in the abdominal wound. If we do not find it there we expect to find it in the pouch of Douglas, and if we fail to find it there, we take x-ray films of the chest in order to see whether or not a subphrenic abscess is present.

I think it is most important to point out that there are no pathognomonic symptoms—merely fever of unexplained origin coming on after operation or peritoneal trauma. That there is a possible etiology for subphrenic abscess in such a case should make us hunt actively for an abscess. If we do that we shall find it much more often, I believe, than any of us suspect.

Dr Faxon pointed out that some 25 per cent of his

cases had evidence of definite subphrenic infection, which, however, did not go on to abscess formation. This shows how carefully he and his confreres follow these cases and points to the need for some delay before operating on early cases.

When I first became interested in subphrenic abscesses, the one stage retroperitoneal approach, which Ochsner describes and Dr. Faxon and his associates advise, was not in common use and we were not familiar with it. We started with the two-stage transpleural method. I still use it, but I feel a little less in favor of it at the present time in view of Dr. Faxon's figures, and because of the obvious good sense of the one stage retroperitoneal approach. We have, however, had very satisfactory results with the two-stage approach.

If you look at the ordinary picture that shows the relation of the parietal and diaphragmatic pleura, they appear to be widely separated. In cases of subphrenic abscess, however, the diaphragm is raised very markedly and the costophrenic angle is reduced or obliterated, and my experience has been that the diaphragmatic pleura and the parietal pleura are usually in close approximation.

Dr. Faxon has emphasized, and I agree, that the great danger in draining a subphrenic abscess is that you will give the patient additional trouble by soiling the pleural cavity and causing empyema. With this in mind, I have found it a good plan to remove 11 cm. or more of the tenth rib in the midaxillary or postaxillary line, suture the diaphragm to the parietal pleura and pack the wound. After twenty-four or forty-eight hours the pleural cavity is walled off. At the second operation there is afforded a large exposure, and one may enter the subphrenic area with freedom and ease and explore it. There should never be postoperative empyema.

I have tried to approach these abscesses on the side by taking out a piece of the tenth or eleventh rib and pushing up the pleura, being careful not to perforate it. I think that this is a highly dangerous procedure, since it is very easy to make a small opening in the pleura. I have noted in Ochsner's article—and I believe Dr. Faxon also says so—that even in the retroperitoneal approach the pleura runs to the level of the twelfth rib and sometimes a little beyond, a place where it is apt to be injured. I am inclined to think that the transpleural approach has advantages, chiefly because the surgeon recognizes that the pleural cavity is in danger and takes care to wall it off, and because there is a large exposure for the second stage, thus facilitating exploration of the subphrenic area and drainage of the abscess.

DR. THACHER W. WORTHEN, Hartford, Connecticut. This is a timely subject, and I agree with Dr. Faxon's conclusions. Analyzing the figures in his series, one arrives at the fact that the yearly average incidence was between 4 and 5 cases. If one eliminates the cases with the diagnosis of subdiaphragmatic inflammation which were not confirmed either by operation or by autopsy, the incidence was only about 3. A series of cases at the Hartford Hospital, covering a ten year period, had nearly the same incidence. The mortality in this group was a little over 20 per cent.

The real problem that the review of these cases revealed was the difficulty of finding the abscess at operation. Three cases were diagnosed at autopsy as subdiaphragmatic abscess, but no pus had been found at operation. In 2 of these cases an anterior and a posterior approach had been made, yet a large collection of pus in the posterosuperior space had not been found.

The surgical treatment of subdiaphragmatic abscess

may be approached from two points of view, the conservative and the radical. A certain degree of conservatism is warranted in some cases in the early stages of the formation of the abscess, because there are cases of so-called subdiaphragmatic inflammation which do subside and for which surgical interference may be unnecessary. Perhaps it is not wholly accurate to call them abscesses in this stage. On the other hand, in the presence of a positive diagnosis of subphrenic abscess, early interference by the extraserous approach, either anterior or posterior, seems the logical one. Dr. Clute's success with the transpleural approach speaks for itself, however, and has given him excellent results. I cannot help but feel that Dr. Faxon has made a real contribution to the subject.

DR. TORR W. HARMER, Boston. This subject is interesting from its anatomical basis, and from the nicety of the Nather-Ochsner operation. In order to appreciate the adult anatomic relations it is necessary to consider the embryology, and to think of the liver as developing between the leaves of the anterior mesentery, which extends to the umbilicus with the umbilical vein in its free margin, and of the early attachment of the liver to the diaphragm posteriorly. Dr. Faxon spoke of the high attachment on the right side. If one follows the peritoneum up the anterior parietes onto the undersurface of the diaphragm, it becomes reflected onto the front face of the liver at the anterior margin of its attachment. If one ascends the posterior parietes, it passes over the right suprarenal gland and then onto the undersurface of the liver. These reflections onto the liver form the two leaves of the coronary ligament.

I think that with this embryological concept one can appreciate the anatomical situation. It is also interesting to do the Nather-Ochsner operation on cadavers, having performed this operation many times with medical students over a period of years, I am impressed with its anatomical nicety.

My own experience since Nather and Ochsner published their contribution in 1923 is meager. I have had only 6 cases, 2 were seen very late, the patients having scaphoid abdomens and being practically "skin and bone." One abscess was in the left posterior space, one in the right anterior space and four in the right posterior space. There were 2 fatalities, in one the abscess was in the right anterior space, and in the other it was in the right posterior space.

One thing which Dr. Faxon mentioned but which is worth emphasizing is the futility of the diaphragm on fluoroscopic examination. I had this impressed upon me by a case in which the diaphragm was pushed up but not fixed. There proved to be a solitary abscess of the liver about 8 cm. in diameter, and not a subphrenic abscess as I had at first thought. The fluoroscopic examination was repeated, and the radiologist still made a diagnosis of subphrenic abscess. I explored anteriorly and drained the abscess, with a successful outcome.

DR. IRVING J. WALKER, Boston. It seems to me that if right-sided subdiaphragmatic abscesses are difficult to diagnose, those on the left are even more so, at least in my experience. I wish to comment on 9 cases seen by me during the last four years. All these occurred following general peritonitis secondary to acute appendicitis. The story in each was similar: that of a patient who had had peritonitis associated with appendicitis. A pelvic abscess was drained in each case. This was followed by a persistent temperature which could not be accounted for.

Naturally we investigated the chest, the right subdiaphragmatic region, and finally, but usually rather late

the left. While this study was going on the patient would have a slight cough and complain of some very indefinite low grade pain in the left upper quadrant. The medical consultants usually said that there were rales at the left base consistent with atelectasis. Of course the latter existed, but, as later events showed it was due to a lesion below the diaphragm. Palpation showed slight tenderness below the left costal border.

X-ray examination done early in the course of the case usually showed a pneumonic process at the left base. The surgeon not being entirely satisfied, would naturally reason that perhaps after all there was a lesion beneath the diaphragm. The diaphragms were not elevated in all cases which did not rule out the possibility that there might be some lesion beneath them. It would seem to me that the important point of the x-ray examination lies in the fact that when the patient was examined under the fluoroscope it was found that the left diaphragm either was fixed or moved only slightly. I therefore lay greater stress on fixation of the diaphragm than I do on its elevation, since fixation occurred in all our cases. Of these 9 cases 8 were discovered and operated on. The ninth was not found until postmortem examination.

Our surgical approach in these cases was transperitoneal. We reasoned that these abscesses occurred as a result of unrecognized pelvic abscesses, or abscesses of the pelvis which had been allowed to remain undrained for too long a period of time, the result being slow seepage from the abscess up the gutter along the outer side of the sigmoid and descending colon, and finally an accumulation of pus under the left diaphragm. We justified our transperitoneal approach because of the fact that our incision would give dependent drainage, and that the peritoneal cavity would probably not again become infected, since it was already immune to the same infection as that which produced the subdiaphragmatic abscess.

All these cases were drained by an incision under the left costal border. We early found that it was necessary to use a large tube or two smaller tubes for drainage, and that we should not remove these tubes too early, other wise we would have a cavity under the diaphragm with a bottle necked sinus which would be insufficient to drain the abscess. From time to time we injected the cavity with Lipiodol, gradually removing the tubes and omitting them entirely when the sinus was very small. All the 8 patients who were operated on recovered.

DR. FAXON (closing). Apropos of what Dr. Clute has said in regard to possible damage to the pleura in the retroperitoneal type of operation, I should like again to stress the points brought out in Figure 6. From the studies of Melnikoff the pleural cavity never extends as low as the level of the first lumbar spine. This being the case, no contamination of the cavity can occur if the fascia be incised along the C-D rather than the line of skin incision and bed of the twelfth rib, A-B.

Another advantage of the retroperitoneal approach that I did not mention is the fact that with this operation both the right posterolateral and right inferior spaces are equally accessible for drainage, whereas with the trans-thoracic approach such latitude of exploration is impossible.

If the anterior spaces are to be drained, care should be taken that the incision along the lower costal margin goes to, but not through, the peritoneum. By blunt dissection the abscess can then be readily reached without entering the general peritoneal cavity.

I agree that it is most important that a sufficiently large opening be instituted and maintained in order to avoid a bottle neck type of abscess and premature blocking of drainage.

HEBERDEN'S NODES THE INCIDENCE OF HYPERTROPHIC ARTHRITIS OF THE FINGERS*

ROBERT M. STECHER, M.D.†

CLEVELAND

HEBERDEN'S nodes are enlargements of the terminal interphalangeal joints of the fingers. Little detailed information concerning these enlargements is available, although they are mentioned frequently in the medical literature. They have been variously ascribed to gout and to rheumatoid arthritis, but it is the consensus that they are due to hypertrophic arthritis. This particular form of hypertrophic arthritis lends itself readily to statistical analysis because it constitutes a clear-cut clinical entity, the diagnosis can be made with reasonable certainty by looking at the fingers, the degree of involvement can be estimated quantitatively, and the disease is relatively common.

Most studies on the incidence of arthritis have been devoted to determining the proportion of the population disabled by rheumatic diseases.¹ Such investigations are of importance from the social, economic and public-health standpoints, but yield little or no information concerning the causes or nature of any particular disability.

The present study is an attempt to evaluate the influence of age, sex, race and occupation on the incidence of Heberden's nodes. It is undertaken with the hope that exact information concerning this particular form of hypertrophic arthritis will reveal characteristics which might not be apparent from studies of the disease in general.

LITERATURE

The syndrome derives its name from Heberden,² who first described it in 1802 as "digitum nodi." His description is so short as to warrant quotation in full. He wrote:

What are those little hard knobs, about the size of a small pea, which are frequently seen upon the fingers, particularly a little below the top, near the joint? They have no connection with the gout, being found in persons who never had it, they continue for life and being hardly ever attended with pain, or disposed to become sore, are rather unsightly than inconvenient, though they must be some little hindrance to the free use of the fingers.

Charcot³ gave a more complete and detailed description of the clinical and pathological characteristics of the disease, based on personal observation. He added that the end of the finger is often

bent a little to the right or left. Usually the onset is very obscure, however, there are attacks of redness, heat and temporary swelling of the soft parts, really exacerbations of the affection which the patients often regard as paroxysms of gout. "These nodosities are interesting to the observer," he said, "because they reveal a constitutional state which is none other than the rheumatic diathesis." Charcot noted that Heberden's nodes belong especially to old age but may be seen in young people, that the disease is hereditary, and that it occurs with partial rheumatism (hypertrophic arthritis). He stated that Heberden's nodes are often accompanied by asthma, migraine, neuralgia and muscular rheumatism, and that they are commonly seen in patients with cancer of the breast.

Duckworth⁴ mentioned that the disease is seen in people of advanced age, and agreed with Charcot that cancers of the breast and uterus are not infrequently associated with it. "When occurring in men without any pronounced gouty or rheumatic concomitant," he wrote, "they may support a general prognosis for longevity." He cited a case in which Heberden's nodes occurred in three generations. Duckworth quoted Begbie to the effect that they are seldom or never seen in the fingers of the industrious laborer or hard-working mechanic, but are found chiefly among the upper classes or the luxurious and well-fed or their dependents.

McCrae⁵ asserted that Heberden's nodes are commoner in advanced years but may occur in younger people. He mentioned a sixteen-year-old boy with large nodes occurring as part of a generalized arthritis. In another patient, a woman thirty-two years of age, the nodes developed rapidly in all the fingers. They may occur as the only manifestation of arthritis. McCrae mentioned the irregular distribution, the usual lack of serious symptoms and the deflection and deviation often seen in the terminal phalanges.

PATHOLOGY

The pathologic changes found in Heberden's nodes have been described by numerous observers. Charcot³ gave an excellent account of these changes. He said:

The articular cartilages undergo the velvety change, then they disappear, and an eburnated osseous layer

*From the Department of Medicine of Western Reserve University School of Medicine at City Hospital, Cleveland, Ohio.

†Senior clinical instructor, Western Reserve University School of Medicine, visiting physician in general medicine, City Hospital, Cleveland.

is found in their place. The articular surfaces enlarge in all directions on account of the growth of osteophytes, which almost exactly reproduce in an exaggerated form their shape and natural contours. There is no trace of sodium urate deposits either in the substance of the articular cartilage or in the soft part in the neighborhood of the joints.

Nichols and Richardson⁶ in 1909 asserted that Heberden's nodes were due to degenerative (hypertrophic) arthritis. Their description of the changes in the cartilage found in degenerative arthritis is quite similar to that given by Charcot. They stated that the changes consisted in an increase in the activity of the perichondrium, resulting in the new formation of cartilage which might be transformed into bone.

Brogssitter⁷ examined histologically the nodes of 17 fingers. He found the characteristic changes of hypertrophic arthritis, namely irregular erosion and fibrillation of cartilage, cystic and fibrotic areas in the hyperemic bone marrow, and spur formation. The most interesting findings, however, were in the small blood vessels. These lesions consisted of typical arteriosclerotic changes with narrowing of the lumen by intimal proliferation and even complete occlusion of the vessels with old and canalized thrombi. The media was infiltrated with round cells, in places to a sufficient degree to lead to rupture of the vessels and hemorrhage into the surrounding tissue. Because of these findings Brogssitter believed that Heberden's nodes occurred as a result of decreased circulation in the bone and disturbance in nutrition of the joint cartilage. He found uric acid tophi in 3 of the 17 fingers examined, but thought that Heberden's nodes in general were due to hypertrophic arthritis.

Stockman⁸ concluded that Heberden's nodes were not a manifestation of osteoarthritis because he "examined a number of specimens all of old standing and did not see the peculiar changes characteristic of true osteoarthritis. In all the joint had remained intact, and the cartilage was normal in appearance."

ETIOLOGY

Before Heberden's time, nodules on the fingers were considered to be typical manifestations of gout. Heberden² did not know their cause but disagreed heartily with the conventional view of the time. Charcot³ believed they were a special form of chronic rheumatism having nothing to do with gout. Garrod⁹ stated that Heberden's nodes might be regarded as constituting the slightest and most chronic manifestations of rheumatoid arthritis, and that their formation appears to be of the nature of a senile change. He employed the term rheumatoid arthritis¹⁰ to include

chronic arthritis of all types. Duckworth⁴ thought that some cases of Heberden's nodes were due to gout, and quoted Begbie, who was convinced of the occasional gouty nature of the disease. Brogssitter⁷ found uric acid tophi in 3 of the 17 nodes examined, but thought that the nodes in general were due to hypertrophic arthritis. Stockman⁸ did not commit himself as to their true nature except to doubt that they were caused by hypertrophic arthritis. McCrae⁵ mentioned their occurrence in gouty patients but believed them to be usually a manifestation of arthritis deformans. Fox and Van Breeman¹⁰ regard the condition as a form of gout modified by sex.

Cecil¹¹ states that Heberden's nodes are a form of hypertrophic arthritis but that the cause is not known. He is convinced that they are related in some way to repeated trauma because they occur most frequently in people who use their hands continually. Cecil does not mention the menopause as a cause of Heberden's nodes, but says that the diagnosis of menopausal arthritis is justified if on examination there is crepitation without swelling of the knees and Heberden's nodes of the fingers. Hench¹² believes that Heberden's nodes are a form of hypertrophic arthritis. Concerning the influence of trauma he writes, "Heberden's nodes are seen no more frequently, indeed perhaps less frequently, in elderly typists and needleworkers than in congenital dowagers contrary to expectation if trauma was a prime cause." Dawson¹³ states that the nodes constitute one of the commonest of all forms of osteoarthritis, and most commentators^{2-5, 7, 10-13, 15-21} agree that they are typical manifestations of hypertrophic or osteoarthritis.

PLAN OF STUDY

This study was undertaken in order to determine the incidence of Heberden's nodes in the general population, analyzed according to race, sex, age and occupation. It reveals the proportion of individuals having several degrees of involvement of Heberden's nodes at any one time in the various race, sex, age and occupational groups. In order to accomplish this object I have examined nearly 7000 adult subjects. Most of these people were seen on the wards or in the dispensaries of two public hospitals in Cleveland. Because of the scarcity of elderly patients in the dispensary and hospital population, the inmates of several homes for the aged were included. Efforts were made to employ random sampling and to avoid bias, so far as possible. Subjects were examined only in groups as in a dispensary waiting room, a hospital ward or a section of an old folks home, and every one of the group was included in the

tabulation Isolated observations were excluded, since it was believed that such observation might bias the results because of the temptation to include occasional, affected individuals to the exclu-

ease had been well and active until a few years before observation, and had therefore led a normal existence until quite recently So far as Heberden's nodes are concerned, I believe that

| CLASSIFICATION | NO OF SUBJECTS IN DIFFERENT AGE GROUPS | | | | | | | | |
|--|--|-------|-------|-------|-------|-------|-------|-------|-----|
| | 10-19 | 20-29 | 30-39 | 40-49 | 50-59 | 60-69 | 70-79 | 80-89 | 90+ |
| 2233 white men (hospital population) | | | | | | | | | |
| Total subjects | 115 | 324 | 306 | 446 | 439 | 353 | 203 | 44 | 3 |
| Affected subjects | 2 | 28 | 27 | 51 | 84 | 101 | 65 | 13 | 2 |
| 2187 white women (hospital population) | | | | | | | | | |
| Total subjects | | 500 | 498 | 512 | 306 | 207 | 125 | 34 | 5 |
| Affected subjects | | 1 | 18 | 34 | 47 | 57 | 51 | 12 | 3 |
| 846 Negro men | | | | | | | | | |
| Total subjects | | 184 | 249 | 191 | 131 | 75 | 16 | | |
| Affected subjects | | 16 | 16 | 20 | 17 | 16 | 3 | | |
| 1117 Negro women | | | | | | | | | |
| Total subjects | | 330 | 346 | 255 | 124 | 48 | 12 | 2 | |
| Affected subjects | | 0 | 9 | 7 | 5 | 8 | 3 | 1 | |
| 530 white physicians | | | | | | | | | |
| Total subjects | 104 | | 147 | 165 | 73 | 34 | 7 | | |
| Affected subjects | 2 | | 7 | 8 | 10 | 5 | 1 | | |

The fact that the group observed was composed of the hospital population and not of normal individuals does not impose any serious inaccuracy for the purposes of the present study, for none of these people sought hospital care because of Heberden's nodes Most of the patients were in good health except for some minor or acute illness which had no bearing on the presence or absence of the nodes Even those with chronic dis-

with a different social and economic group the study includes a tabulation of over 500 physicians.

TECHNIC

Notations were made on a separate card for each subject, the name, race, sex, age and the abnormalities of each finger being recorded The positive and negative cards were separated, and each of these groups was then sorted as to race, sex and

age by decade. The cards were filed alphabetically in the proper classification. When a subject was seen for the second time, this card was found upon filing to be a duplicate and was discarded.

Three degrees of involvement of affected fingers were described by a simple system of notation. These are, in the order of increasing severity, as follows: enlarged, enlarged and flexed, enlarged, flexed and deviated. Enlargement of the joints sufficient to be visible and palpable was considered necessary for a diagnosis. This enlargement is occasionally apparent as two small nodules on the dorsolateral aspect of the terminal joint, but

As experience accumulated during the progress of these observations it became apparent that Heberden's nodes developed in two different ways. Individuals with involvement of only one finger or of several fingers of the same hand usually attributed the deformity to a definite injury. Trauma resulted in swelling and pain followed shortly by deformity that reached its final stage within a few months, after which no further change occurred. This condition has been designated as *traumatic* Heberden's nodes.

Individuals with the fingers of both hands deformed usually stated that the disease began with

more frequently is noted as a definite ridge across the dorsum. At times enlargement is found to be soft or even fluctuant. When the disease occurs in a more advanced form, this enlargement extends to the lateral aspects of the joint also, and finally in extreme cases is evident by palpation on the palmar surface. As enlargement increases the bone deformity is associated with flexion of the terminal phalanx. In advanced stages the finger shows not only palmar flexion but also lateral deviation toward either the radial or the ulnar side. In rare cases there may be involvement of the proximal interphalangeal joint, evidenced by the presence of deformity, enlargement and limitation of motion.

The description thus far has concerned a single finger. Several fingers are often involved. The degree of involvement affecting the different fingers varies considerably, but rarely are all the fingers involved to an extreme degree. The thumbs seem to be comparatively immune, perhaps because there is no second interphalangeal joint of the thumb. Involvement of the toes has not been observed.

pain and swelling of one finger, that other fingers became successively involved that deformity gradually increased and that the disease progressed for several years until the condition became stationary. In this group the changes seemed to arise spontaneously without reference to injury or associated disease, and the condition has therefore been designated as *idiopathic* Heberden's nodes.

For the purposes of statistical study, an arbitrary distinction has been made between the traumatic and idiopathic nodes. Subjects with involvement of less than flexion degree of one finger of each hand have been considered to have traumatic Heberden's nodes. Subjects, therefore, who had involvement at least to flexion degree of one finger of each hand were considered to have idiopathic Heberden's nodes. Inasmuch as histories were not obtained from these subjects (except for the information recorded on the card), an exact discrimination in individual cases was not possible. It must be emphasized that this differentiation into traumatic and idiopathic nodes is only ap-

proximate, but it serves a useful purpose in distinguishing degree of involvement, and reveals certain definite trends which seem significant

Figure 1 illustrates the typical appearance of Heberden's nodes. The fourth fingers show only

The observations upon which this study is based are presented in two tables and a chart. Table 1 shows the total and the affected subjects observed in the different race, sex, age and occupation groups. Table 2 presents the same material in

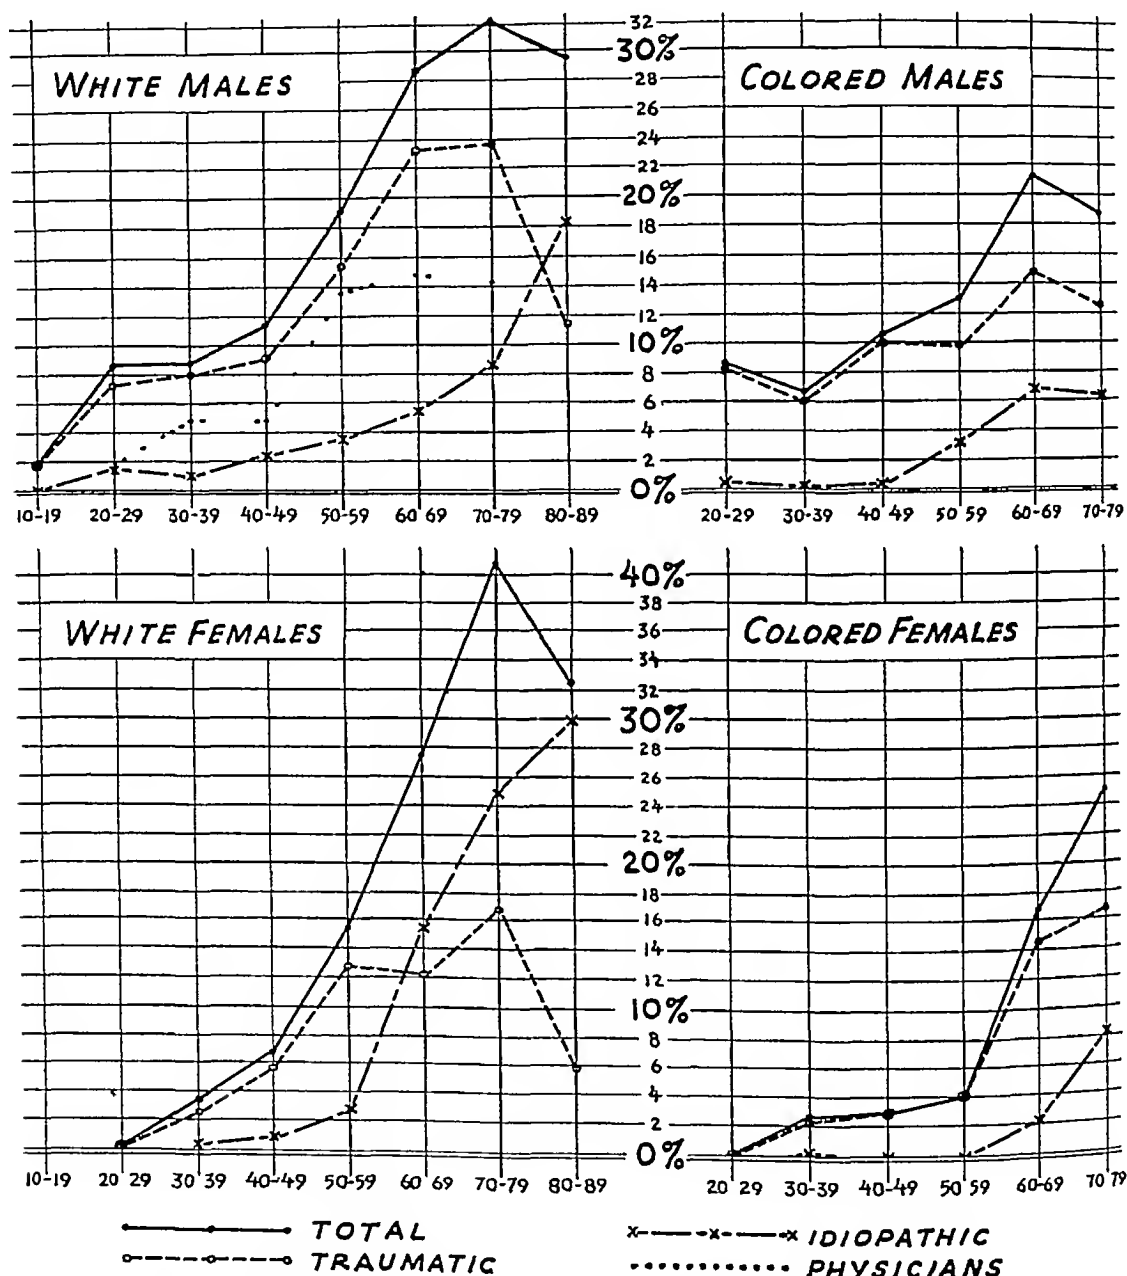

FIGURE 2 The Percentage Incidence of Heberden's Nodes in 6913 Subjects, Classified as to Race, Sex, Age and Occupation

The total incidence has been subdivided into traumatic and idiopathic for all groups except physicians

enlargement of the terminal joint. The other fingers show flexion deformity as well as enlargement. The index fingers show also lateral deviation of the terminal phalanges. The condition of any one of these fingers might have resulted from trauma. It is extremely unlikely that trauma affected all of them. The picture is one of idiopathic Heberden's nodes.

percentage form. The total incidence and the incidences of traumatic and of idiopathic nodes are indicated for each subgroup. The information in Table 2 is presented in graphic form in Figure 2, because of the small number of persons, the white subjects over the age of eighty-nine and the colored subjects over seventy-nine have been omitted. The percentages in the last-mentioned

groups are completely out of line with the trend in the other classification. The group of physicians observed between the ages of seventy and seventy nine was similarly small, but has been included because all the groups in the physicians are small and the last named group conforms to the general trend. It will be seen that twenty four of the thirty six age groups shown in Table 1 include 100 or more individuals.

DISCUSSION

Several possible sources of error in this study deserve mention. The problem of diagnosis in borderline cases is so different in this condition from what it is in any other disease. Inasmuch as the observations were all made by me the same rules and the same criteria prevailed in all observations. Clubbing of the fingers is never a source of confusion. In this condition the enlargement is confined to the terminal phalanx, the enlargement is greater at the end of the phalanx than it is at the joint, and the fingernail is distinctly enlarged and rounded in both diameters. Two other conditions are more puzzling and caused some difficulty in the beginning. One is flexion of the terminal phalanx without arthritis or enlargement of the joint, which occurs with rupture of the deep extensor tendon. Ability to extend the terminal phalanx is lost, but passive extension is full and complete. Deviation of the little finger occurring symmetrically as a hereditary trait is also without enlargement or arthritis of the joint. Certain sources of statistical error are worthy of comment. No note was made of missing fingers. Patients with one hand, 1 with claw hands and 1 with webbed fingers were omitted.

The age in every case was recorded as given by the subject. Many Negroes are uncertain as to their exact age and seem to be careless in their statements concerning it. It is thought that middle aged white women are inclined to underestimate their age. These inaccuracies cause no practical difference and introduce only a slight statistical error. According to the system of tabulation used, no error whatsoever is introduced unless the age is given in the wrong decade. The classification according to race is social rather than anthropological.

Trauma

Trauma is a definite cause of many cases of Heberden's nodes, especially in subjects with involvement of one finger or of several fingers of one hand. Inquiry recalled a specific injury often accurately dated, directly involving the affected fingers. Such injury was followed by a painful swelling, leading in the course of several months to a painless deformity, which remained un-

changed thereafter. Baseball injuries, such as a blow on the end of the finger by a fast ball, were predominant among younger men and boys, but were also described by older individuals. One subject with deformities of most of the fingers of the left hand said that he had been a left handed catcher. Another subject, aged sixty five, with deflection deformity of the right forefinger, had suffered a dislocation of that finger forty five years previously when struck on the end of the finger by a fast-pitched ball. No change had been noted in this condition since the first few months after the accident. Several women with one enlarged finger attributed it to a baseball injury. Injuries received in other sports, such as football, basketball and skating, were followed by similar results. Industrial accidents played an important role. It was not uncommon to find cases of traumatic amputation with Heberden's nodes on the adjacent fingers.

The inclusion of traumatic arthritis of the terminal interphalangeal joints in the category of Heberden's nodes is justified. In this study any enlargement of these joints due to hypertrophic arthritis is considered as Heberden's nodes, and traumatic arthritis is considered to be hypertrophic arthritis. According to Doub,²² traumatic arthritis has come to mean those chronic changes, such as synovial thickening, necrosis of the cartilage with narrowing of the joint space, and bone proliferation, which resemble arthritis and occur in and around a joint after injury. This arthritis simulates the type which goes by the name "hypertrophic (osteoarthritis or arthritis deformans)." Doub further states that traumatic arthritis must satisfy the following criteria: there must be proof of injury and of its severity; the injury must have been applied directly to the joint in question; information must be obtained as to the previous function of the joint in question; the time interval between injury and the occurrence of pathologic changes must be within the generally accepted limits (three to six months or perhaps a year); there must be clinical and roentgenologic evidence of pathologic tissue change. Doub quotes several authorities (Axhausen, Engelhardt and Blencke) who believe that injury must be severe enough to damage cartilage before traumatic arthritis ensues. Leriche,²³ on the other hand, believes that traumatic arthritis results from cartilage damage due to a hyperemic reaction following local traumatic shock. Allison and Ghormley²¹ state that true traumatic arthritis is indistinguishable microscopically from degenerative arthritis. Traumatic Heberden's nodes conform to all the requirements of traumatic and therefore of hypertrophic arthritis.

The histories obtained from subjects with idiopathic nodes are in striking contrast to those obtained from subjects with traumatic nodes. In the former cases no history of injury can be elicited. The nodes arise spontaneously without coincident illness or recognizable predisposing cause. The affection of one finger is followed by involvement of more fingers one after the other for a period of months or years. In the beginning swelling may be soft or even fluctuant, there may be slight redness and tenderness, but these symptoms disappear when the final nonprogressive stage of the deformity is reached. The so-called wear and tear of everyday life has been blamed, especially in people who have worked hard, but this is an unsatisfactory explanation. The condition occurs in hard-working people, as this survey indicates, but severe Heberden's nodes are frequently encountered in women of the leisure class. Further consideration of the constitutional and environmental factors in the etiology of idiopathic Heberden's nodes will be discussed in another study. It should be noted that it is impossible to distinguish in a single joint between traumatic and idiopathic Heberden's nodes by clinical and roentgenological examination alone and without reference to the history.

The arbitrary classification into traumatic and idiopathic Heberden's nodes necessitated by inadequate history of the subjects of this inquiry leads to individual cases of error. Certain it is that some individuals develop nodes on the fingers of both hands as a result of trauma and are erroneously classified as having idiopathic nodes. Conversely, subjects developing idiopathic nodes are occasionally seen in a stage when only one finger or several fingers of the same hand are involved and are classified erroneously as having traumatic nodes. Such errors are in the opposite direction and tend to cancel the previous ones. A curious effect of what may be inaccuracy of classification is seen in the chart concerning white subjects. The incidence of idiopathic nodes increases gradually until a certain age,—seventy-nine for men, fifty-nine for women,—after which the incidence increases very rapidly. Coincident with this rapid rise of incidence of idiopathic nodes, the incidence of traumatic nodes falls. It seems possible that the apparent increase of traumatic nodes before this trend is altered may in reality be due to the development of idiopathic nodes which have not reached the stage at which they are recognized as such. Even though the arbitrary classification into traumatic and idiopathic types may introduce certain errors, the figures on the incidence of the different degrees of severity of

Heberden's nodes are believed to be thoroughly reliable.

Age

Age is a definite factor affecting the incidence of Heberden's nodes, the incidence increasing as age advances. This is demonstrated for both idiopathic and traumatic nodes, regardless of sex, race or occupation. Heberden's nodes are seen in the third decade among all groups except Negro women. They are seen in the second decade in white men, the only group in which this age was investigated. Traumatic nodes are common in men, even at early ages, and are relatively rare in women. They increase with advancing years in almost every group, though the rate of increase is irregular and varies in different groups. Idiopathic nodes are rare at early ages, the incidence shows a gradual and regular increase with age. After the age of fifty-nine in white women and sixty-nine in white men and Negro women the increase is more rapid. Heberden's nodes are permanent deformities which, once developed, remain for life. The incidence is cumulative, and each new increment, as it occurs, is added to the increment already present. In any group of the population, the incidence will increase with advancing age so long as the factors causing them are operative.*

Sex

Sex is an important factor in determining the incidence of Heberden's nodes, in both white and Negro subjects. The incidence of traumatic nodes is higher in men than in women as early as the third decade, and increases at a higher rate throughout life. This difference can be attributed to environmental factors rather than to true sex differences. The educational, recreational and occupational activities of men differ considerably from those of women. The sports which they enjoy, baseball, football and basketball, are much more likely to produce finger injury than are those in which women usually indulge. In the shop, the fingers of many men are constantly exposed to industrial accidents. Men and women seem to be equally exposed to certain injuries in their homes and private lives which lead to Heberden's nodes, such as pinching of the fingers in doors and other minor household accidents.

Race

A comparison of the incidence of Heberden's

*Even in the face of these conditions a decreasing incidence in advanced years is a theoretical possibility. Two conditions would be necessary. The presence of Heberden's nodes would have to be associated with an increased death rate to such an extent that these subjects would disappear faster than that part of the population which was free of Heberden's nodes, and faster than new cases developed. Such was not the case, however, among the subjects examined.

nodes in white and Negro subjects reveals certain differences. The gross incidence is higher in Whites. The difference is slight before the age of fifty, after which it becomes substantial. In men, this difference is almost entirely due to the markedly higher incidence of traumatic nodes in Whites. In women the incidence of traumatic nodes is essentially the same in both races except in the fifth and six decades, in which white women are affected respectively two and three times as frequently as Negro women. The incidence of idiopathic nodes in white and Negro males is essentially the same at all ages. Idiopathic nodes are rare in Negro women, in contrast to the high incidence found among white women. This is surprising in view of the fact that Negroes are more susceptible than are white people to the so-called degenerative diseases. The death rate from chronic nephritis, organic diseases of the heart, cerebral hemorrhage and other diseases of the arteries is distinctly higher among Negroes^{21, 22} than it is among white people. Negroes are said to succumb to hypertensive heart disease on the average ten years earlier than do Whites. Despite the susceptibility of Negroes to disease of the small arteries, and the evidence that small artery disease is a factor in the production of Heberden's nodes, this condition is rare among Negroes.

Occupation

Occupational factors seem to affect the incidence of Heberden's nodes only in so far as they influence the hazard of finger injury. The gross incidence in physicians is distinctly low in all age groups. The incidence of traumatic nodes in physicians is one half or less in all age groups save the sixth decade, in which it reaches two thirds. The difference in the third decade is striking. It appears that this decade is specially hazardous for workmen, so far as finger trauma is concerned. At this period of life physicians are in medical school, in hospital service or early practice. They have relatively little time for athletic sports and they are finger-conscious. The incidence of idiopathic nodes in physicians, while lower, appears to be approximately the same as that found in workmen. This suggests that environmental factors, working conditions, housing, clothing, diet and other refinements of living are not important in the production of Heberden's nodes. The number of physicians observed in the upper age groups is so small as to cast considerable doubt on the reliability of the figures for idiopathic nodes.

General Considerations

Observations on a large number of individuals

of various ages have revealed the incidence of Heberden's nodes. Similar results would be obtained by observing the incidence of Heberden's nodes as they occur at different ages in a large group of individuals who are examined repeatedly and periodically. From a statistical standpoint, and so far as Heberden's nodes are concerned, we may assume, for instance, that the white working males seen in the seventh decade present a picture similar to that which the white males of the third decade will show forty years later. We have, so far as Heberden's nodes are concerned, repeatedly observed the equivalent of five different groups, each numbering several hundred individuals, over a period of fifty or sixty years.

The probability of an individual's having hypertrophic arthritis of the fingers (Heberden's nodes) has been demonstrated, to increase with age. Although the rate of increase varies considerably in the different classifications, the trend is apparent in each of the sex and race groups. Glover²³ found an increasing incidence with advancing age in a clinical study of hypertrophic arthritis in general. Heine²⁷ and Keefer et al²⁸ have demonstrated it in extensive pathological studies of other human joints. There is experimental evidence of an increased susceptibility to degenerative joint disease with age. Pemberton et al²⁹ were able to produce bony spurs on the patellas of old dogs by interference with the blood supply but were relatively unsuccessful when working with young dogs. Despite these findings, the present study reveals that hypertrophic arthritis of the fingers occurs in the second decade in white men, in the third decade in white women and Negro men and in the fourth decade in Negro women.

SUMMARY

Heberden's nodes (enlargements of the terminal finger joints due to hypertrophic arthritis) occur as a result of direct trauma or arise idiopathically.

A clinical history permits accurate differentiation of these two types, which may otherwise be indistinguishable. An arbitrary classification, based on degree of involvement has been adopted for this study.

The incidence of both types was determined by examination of nearly 7000 individuals. The incidence was analyzed according to race, sex, age and occupation.

The incidence of both types tends to increase with age in all groups.

The incidence of traumatic nodes is higher in men than in women, is higher in workmen than in physicians, and is higher in white working people than in Negroes. The differences be

tween various groups of white people seem to depend on differences in exposure to finger trauma

The incidence of idiopathic nodes is universally low before the age of sixty, after which it increases very rapidly in white women. It increases much more slowly in workingmen of both races, but remains very low in Negro women.

The low incidence in Negroes of both types of Heberden's nodes is not readily explainable.

DELINQUENCY*

DOUGLAS A. THOM, M.D.†

BOSTON

CRIME, of all the social problems, is the most interesting. The fact that so many different types of people of all ages are fascinated and intrigued by a criminal career that it is portrayed from many different angles in books, at the theater, on the screen and over the radio, bears witness that crime makes a strong emotional appeal to the masses.

Poverty may be more widely distributed, affect more people, cause more real deprivation, be fundamentally more important as a social problem, but compared with crime it is drab, ordinary, lacking in thrills and held in the contempt which familiarity is said to breed.

Disease, too, as a social problem is without much romance. It may awaken pity or disgust. As a topic of conversation it is often evaded or prohibited as was the public discussion of social diseases until recently. There is a certain morbidity about disease that precludes it from becoming a

subject of universal interest. Not so with crime. The more vicious, the more frightful, the more disgusting, the more demoniacally ingenious it may be, the more it is publicized and accepted as a topic for barroom or drawing-room conversation. An atrocious murder by a feeble-minded delinquent would receive more news space than would the discovery of the cause of some baffling disease. Journalists are in the business of giving the public that which it wants and for which it is willing to pay.

There is probably no one answer to the universal interest in crime. One individual is intrigued by the ingenuity with which a particular crime has been carried out. Another is concerned with the sociopolitical aspects of crime in general and the fact that as a business crime has become well established and relatively safe. Some people unquestionably derive a degree of vicarious satisfaction through their interest in the criminal activities of others. In this way they are able to enjoy the freedom from restraint expressed by the anti-social activities of the criminal group, yet remain innocent themselves of open defiance of authority.

*Read before the Fourth New England Conference on Probation, Parole and Crime Prevention, Portland, Maine, September 29, 1939. From the Habit Clinic for Child Guidance, Boston.

†Professor of psychiatry, Tufts College Medical School; director, Habit Clinic for Child Guidance, Boston.

and immune to the fear of detection and the feelings of guilt which participation in criminal behavior would invoke. There is no doubt that a large number of highly respected, law abiding citizens harbor repressed desires to indulge in asocial activity, and find in the criminal activities of others an outlet for these desires. Crime is no longer the activity of the isolated individual. It has become so well organized, so carefully planned, so skillfully executed and so cleverly protected that it must be considered in the light of an epidemic that requires searching investigation in order to determine the source of the contamination, as well as the detection, confinement and treatment of the individuals involved.

There is also a small group of people who go a step farther and attain what appear to be strange thrills through identifying themselves with crime and the criminal activities of others, owing to a strong unconscious urge for adventure or revenge, or perhaps merely the desire to put themselves across after repeated failures along socially approved lines. These individuals are the so-called psychopaths. There are many and varied reasons for this morbid psychopathic interest in crime. It is generally recognized that there is no common background for crime, and that we can not draw any sharp line of demarcation when we consider the varied groups into which criminals fall. Each and every person committing a criminal act must receive individual consideration. However, for purposes of understanding crime as a problem affecting society, we recognize that there are common factors which stand out and appear to give value to an attempt to make some generalizations about the more important biological, sociological and psychological aspects of crime.

The delinquent and the criminal are individuals whose concepts of right and wrong are out of harmony with those of society. There invariably exists a discrepancy between what the delinquent feels he is entitled to in life and what society allows him to have. The aggressive, non-conforming individual, in his effort to evade, avoid or defy the rules and regulations set up by the community in which he lives, eventually finds himself in conflict with the police, probation officer, truant officer and others appointed to maintain so-called law and order.

Delinquent careers do not begin, however, with the child's first contact with the truant officer or the neighborhood policeman, nor do they end after the child has been apprehended and brought before the judge in a juvenile court. Delinquent activity of the chronic type, characteristic of the individuals who fill our correctional institutions, which eventually develops into a life of crime, is

not the product of a few days or weeks. The state of mind, the habits, the attitudes and the personality traits that are the basis of criminal careers are in the process of development for years before they receive the official and legal stamp which marks the criminal. In other words, the fundamental basic factors, whether they be biological, sociological or psychological, are usually operating 10 or on the individual years before his behavior takes on a definite overt criminal pattern.

Every delinquent and criminal must be considered in terms of his own particular and oftentimes peculiar personality make up, as well as the varied environments and contacts with all their pitfalls and hazards, but for the purpose of acquiring a better orientation to the more important contributory causes of crime, I shall consider for the moment the three main groups in relation to the etiology of crime.

The first is biological and is conditioned by the inherent physical defects or instabilities that are frequently associated with criminal careers and that when operating under certain conditions must be looked upon as being the leading contributory cause.

Mental defectiveness as a cause of delinquency has long been recognized, and its importance as a causative factor has swung through a wide arc. During the early days when psychological tests were being received with unbounded enthusiasm mental deficiency was given the most important place in the etiology of crime. For example, Sutherland,¹ on reviewing the statistics on this subject, found that from 1910 to 1914 there were 50 per cent feeble minded patients among delinquents from 1915 to 1919 28 per cent from 1919 to 1924, 21 per cent and from 1924 to 1928, 20 per cent. The last figure is a fairly conservative estimate of the frequency of mental deficiency among delinquents, but it is necessary to point out that as a cause of crime it must not be considered alone but must be studied in relation to other factors.

The relation between mental retardation and juvenile delinquency should not be difficult to determine. However in the literature there does not appear to be any consensus on the subject. Thompson, of the Department of Hospitals, Psychiatric Clinic, Court of the General Sessions, New York City states "The percentage of defectives is no greater among criminals than among the civil population. Therefore, mental defect cannot be given a prominent place as a factor causative of crime." On the other hand, Glueck,² in her investigations relating to mental retardation and juvenile delinquency, states

(1) There is a far higher proportion of children of lower intelligence among delinquent groups than

in the general population of children, (2) the likelihood of delinquency among children of lower intelligence is greater than among those of higher intelligence, and (3) the families of young delinquents of lower intelligence are far less able than those of higher intelligence to participate constructively in any program for the supervision and treatment of such children

My own experience would lead me to agree with Glueck's conclusions. In a recent study of a group of predelinquent children which were followed up over a period of ten years or more, I was impressed with the fact that there was a far greater tendency for the predelinquent children under ten years with low IQ's to continue a life of delinquency than there was for the children with high IQ's. This does not necessarily mean that a poor intellectual endowment of itself is the cause of delinquency. It does mean, however, that under the existing social and economic conditions these children are subjected to stresses and strains of life of such a nature and of such intensity that failure to meet them successfully is almost inevitable, unless they are given special aid in making a place in the social and economic world.

Mental disease, although rarely diagnosed in children during the first decade, is undoubtedly in the process of development, and some of the strange, peculiar, unpredictable behavior during this early period, as well as the less obvious evidences of personality disorder, are but the beginnings of mental abnormalities. The inherently shy, diffident, shut-in type retreats from the scene of conflict and evades competition by protecting himself with a neurosis, while the more aggressive often finds delinquency an avenue of escape.

In passing, one can only mention the asocial activity associated with epilepsy, encephalitis lethargica and the abnormal behavior which frequently follows damage to the nervous system occurring at all ages.

Considerable attention has been given to the role which the endocrine glands play in affecting behavior. Lurie⁴ found that 20 per cent of the behavior disorders studied at the Child Guidance Home in Cincinnati, Ohio, showed endocrine disturbances, and that in 93 of the 1000 cases studied there was a direct relation between the glandular dysfunction and the behavior difficulty. Rowe,⁵ in his analysis of 104 cases of behavior disorder in children, found that 68 had an associated endocrine disorder. Whether or not these figures exaggerate the extent to which glandular dysfunction is associated with behavior is not so significant as the fact that careful investigation of the physical side of the child's life is of importance.

The psychiatrist as a specialist in the field of mental aberrations, and as a physician, has a

valuable contribution to offer in this particular field. Therapy so far as these biological defects and acquired handicaps are concerned depends very largely on the early recognition of the problem in order that adequate study, treatment, care and supervision can be instituted. Recidivism should be materially curtailed by the early recognition of the group of delinquents who are not likely to profit from experience. Victims of crime, grief-stricken parents and irresponsible delinquents would all profit by an early recognition and an intelligent plan of supervision. The defectives as a group are problems only when poorly adjusted*. When they are recognized early, a plan for training can be instituted which will permit many of them to fit into a social scheme of life on a certain level so that they may evade competition with those intellectually superior, and avoid inevitable failure, which so frequently leads to delinquency. One must keep in mind that crime is not being considered as a biological problem *per se*, but that the fact is being recognized that there exist biological handicaps which are conducive to criminalistic behavior.

The largest and by far the most important group in our etiologic classification are those delinquents whose asocial behavior can be attributed to a very large extent to sociological factors which need not be considered permanent, inevitable or irresistible to change. In fact, demonstrations⁶ have already been made showing conclusively that the delinquent rate in certain city areas is many times higher than it is in others, that in some of these areas as many as 15 to 25 per cent of the boys between the ages of ten and seventeen are arrested for delinquency in any one year, and that approximately 43 per cent more of the delinquents in the delinquency areas are recidivists than in the outlying neighborhoods where the rates are relatively low. Furthermore, delinquency rates can be reduced by improving the sociological conditions under which these individuals have to live.

I need not enter into any prolonged discussion at this time as to the relative importance of environment and heredity, since I am not embarking on a dissertation to prove that environment and its sociological pitfalls are the cause of all delinquency. I am simply stating that as one of the leading factors contributing to delinquency, they warrant serious attention. It is an undisputed fact, and has been shown over and over again, that delinquency is frequently associated with poverty, vice and disease.

*Dr. Walter Fernald, a keen student in the field of mental defects, entertained the idea for years that mental deficiency was relatively rare, that defectives were all potential delinquents and that they should all be in institutions. With the courage characteristic of a great man in the latter part of his life he reversed these opinions and conceded that while there were many defectives few were bad and only a small portion should be in institutions.

A brief review and comparison (Table 1) of the results found in two investigations—the first by the Gluecks,¹ in which the social background

TABLE 1 *Effect of Social Background.*

| SOCIAL BACKGROUND | WELL-ADJUSTED GROUP | DELINQUENT GROUP |
|--|---------------------|------------------|
| | % | % |
| Home and neighborhood: | | |
| Home conditions average or better | 78 | 38 |
| Neighborhood conditions average or better | 95 | 15 |
| Economic status: | | |
| Families dependent or on verge of dependency | 13 | 76 |
| Employment of mothers: | | |
| Mothers gainfully employed | 14 | 42 |
| Nativity of parents: | | |
| Nati-born parents | Over 60 | 20 |
| Education of parents: | | |
| Illiteracy | Less than 1 | 29 |
| Attended or graduated from high school | 46 | 10 |
| Attended or graduated from college | Over 29 | 1 |
| Age of parents at marriage: | | |
| Mean age of parents | 3 | 3 |
| Mean age of younger parent | 25.5 | 21.5 |
| Difference in parents' ages: | | |
| Mean difference in age between parents | 3 | Almost 6 |
| Marital adjustment: | | |

| Contact with social agencies: | | |
| No contacts with agencies | 8 | 13 |
| Broken homes: | | |
| By death of one parent | 19 | |
| By divorce | 2 | |
| By death of one or both parents | | 27 |
| By desertion, separation or divorce | | 19 |
| By criminality of one or both parents | | 20 |
| Size of families: | | |
| Large family (5 or more children) | 11 | 58 |
| Mean number of children per family | 2.93 | 4.98 |

of a group of juvenile delinquents was presented and the second by Thom and Johnston,² in which the social background of a group of well-adjusted adolescents was studied—indicate at least the importance of environment and the contribution that it makes to the development of habits, attitudes and personality traits, and other indefinable mental and emotional characteristics that tend to produce stable, conforming, happy, efficient and mature adults, on the one hand, or asocial, non-conforming, law evading delinquents, on the other.

Striking as these statistics are, one should not jump to the conclusion that bad neighborhoods, poverty, broken homes, alcoholic fathers and psychopathic mothers are necessarily the cause of criminal careers in all the Gluecks' cases, or that the preponderance of good homes, sober industrious parents and happy marital situations necessarily produces well-adjusted children. There would be too many exceptions to such a rule to allow any but the most glib to be satisfied with such an answer. Nevertheless, it cannot be ignored that when certain types of children are subjected to these contaminated social situations, it is just as natural and normal for them to turn toward delinquent careers as it is for them to

learn to speak English when brought up in an English speaking home.

I was much impressed by the statement by Partridge,³ of the Boy Scouts of America, which reads as follows:

In the great majority of cases young people are measured against an adult scale which is quite foreign to them and not in keeping with the set of values they are maintaining with their immediate associates. The fact that they are more disposed to follow the edicts of their fellows than respond to the intangible will of the law, is not difficult to understand because of the definition they have accepted of themselves. It is very important that the individual maintain this with his own immediate group. A happy adjustment to their associates is of relatively greater importance than the possibility that they will be punished by adult society. As a matter of fact, it is not uncommon for groups of young people to consider it an honor among themselves to come into open conflict with the law. The nature of the law is painted to them as a force which is against their own interests—it chases them off the streets—it makes them go to school—it punishes them when they are caught. Keeping in good with their gang and still not getting caught comes to be a game, and those who are the most successful in playing it become the heroes of the group.

And thus it is that young people come into delinquent acts in the most moral and natural way that can be imagined. It is not as if they deliberately planned to run adverse to society. Young people usually get into trouble in the pursuit of natural impulses arising from their own biological needs. In following the traditions of their own group, young people carry on until certain numbers of them are caught up in difficulties. The great majority outgrow these tendencies; those who do not become our chronic delinquents. Many would outgrow their difficulties if given half a chance. Some are definitely started on a career of crime by the way in which they are treated when they get into minor trouble.

Psychiatry as a branch of medicine is concerned with mental aberrations, whether they be emotional or intellectual, not only those which prevent the individual from making the necessary adjustments to life so that he can conform in a satisfactory way to his environment and live in harmony with the group, but also those emotional states which create internal conflict and interfere with the individual's happiness and efficiency.

Mental hygiene is the preventive aspect of psychiatry, and is concerned with the development and preservation of mental health. Mental health is a state of mind which permits the individual to approach his maximum efficiency and to attain the greatest amount of happiness out of life with a minimum amount of friction, anxiety and guilt.

The administration of the principles underlying mental hygiene need not necessarily be confined to the realm of the psychiatrist, any more than physical hygiene needs to be administered exclusively by a physician. In fact, I believe that until men

tal hygiene can be reduced to such terms that it can be utilized in the everyday practice of the parent, teacher, nurse, physician, probation officer and others concerned with the training and education of children, it will not serve a very useful purpose or affect advantageously an appreciable portion of the general public. Such a concept of mental hygiene in no way relegates the psychiatrist to obscurity. There are a sufficient number of intricate, involved, complex problems in the field of delinquency that cannot be interpreted in terms of the individual's environment where the case-work method of the sociological school fails to fathom the depth of the inner strivings, frustrations and phantasies, and the morbid, distorted, twisted operations of a sick mind.

If delinquency is to be prevented, the attack must be made at its source, during the predelinquent stage, when character is in the process of development. During childhood the habits, attitudes, personality traits, opinions, beliefs, concepts of right and wrong, sense of responsibility and feeling of obligation to those other than self are being incorporated in the fabric of the individual's personality. The first decade, particularly the preschool years, is by far the most important in this respect. There can be no substitute for home training, not even in the school or church, much less the psychiatric clinics and juvenile courts. Probation and all the other valuable and influential agencies which have resulted in our new philosophy toward delinquency are but aids after the individual has failed to attain his place and adapt himself to the demands of his environment.

There is no doubt that in an effort to prevent or perhaps minimize the effect of these adverse sociological factors, mental hygiene and the application of psychiatric principles have a contribution to make. Frequently the underlying motivating forces, such as inferiority feelings, resentment toward authority, rebellion against dependence and such unhealthy emotions as jealousy, cruelty, pugnacity, revenge, which are subsequently manifested toward society, were originally unconsciously cultivated toward and because of individual circumstances and conditions operating during the early years. The psychiatrist working directly with the individual may so reorient his point of view, as well as that of the adults who play a vital role in his experience, that the sociological readjustments brought about by the case worker will be acceptable. This psychological approach of preparing the child for accepting new habits and attitudes toward the improved social conditions under which he may be permitted to live need not necessarily be turned over to a psychia-

trist or a clinic. As stated before, these principles must be reduced to such terms as can be practiced by all those who are exerting an influence in the development of the child.

To psychiatry and other allied groups belong those cases of delinquency resulting from biological defects and acquired handicaps of a physical or mental nature, where wise and practical therapy for the delinquent and protection to society depend almost entirely on making the correct diagnosis. Therapy as indicated in these cases must be carried out in co-operation with parents, teachers, social workers, juvenile court judges and probation officers, and not infrequently under the medical direction and occupational supervision that can be rendered only in a well-organized institution.

More strictly confined to the field of psychiatry are those delinquents whose asocial activities result from mental aberrations due to psychological causes. Delinquent or nonconforming behavior is not so different from conforming behavior psychologically as it is socially. All behavior represents an effort on the part of the individual to find satisfactory outlets for a varied sort of ill-defined emotional drives—desires, appetites, urges, call them what you will. When inherent limitations, social conditions, economic deprivations and excesses of mental stress and physical strain have imposed restrictions and subjected the individual to failure that is as inevitable as it is continuous, the usual socially approved adaptations to life break down, and conflicts, frustrations, repressions, fears, obsessions and resentments begin to dominate the individual, affect his behavior and create an unhealthy, distorted outlook on life. When these psychologically and sociologically induced forces create a situation which the individual can no longer cope with in a normal, rational way, something happens. It may be a convulsive explosion, a hysterical paralysis, or a more elaborately developed neurosis with many incapacitating and protective symptoms (all physical expressions of mental conflict), or perhaps these conflicts may express themselves in abnormal conduct of which delinquency may be a manifestation.

It is especially in the study and investigation of these peculiar, apparently unreasonable expressions of mental conflict that psychiatry has a contribution to make. Psychiatry is not a panacea in the treatment of delinquency. There is ample evidence of the limitations which our lack of knowledge regarding human nature has imposed. Psychiatry has, however, during the last two decades evolved an approach to the study of delinquency comparable to that utilized in the field of general medicine. Psychiatry is primarily concerned with

the delinquent rather than with his delinquency. It shares with medicine the scientific point of view that leads to the search for the cause rather than being preoccupied with the symptoms.

The early stages in the development of a delinquent career are as well marked as they are in the development of a disease process. It is regrettable, however, that we have not a few of the instruments of fine precision to measure and evaluate our findings in dealing with human conduct as we have in physical research. There is no sharp line separating the psychological from the sociological approach in the study of delinquency and its prevention.

REPORT ON MEDICAL PROGRESS

THE VITAMINS*

ARNOLD P. MEIKLEJOHN, B.M. (Oxon)†

BOSTON

IN TWO previous reviews^{1,2} appearing in this series, an attempt was made to give a brief summary of present-day knowledge regarding the vitamins. This field is developing with such rapidity at the present time that what was written a year ago is already behind the times in several respects. The following supplementary review has therefore been prepared to bring the previous summary up to date.

VITAMIN A

Interest in vitamin A deficiency continues to center in the important subject of nutritional night blindness. The problem of measuring correctly the degree of subnormal adaptation to darkness is still the subject of extensive research. So far there is no general agreement as to the best procedure and the type of instrument most suitable for this purpose. Critical reviews of the difficulties involved will be found elsewhere.^{3,4} Until the method is standardized and the correct interpretation of the readings is more clearly defined, it would seem inadvisable to adopt such procedures as an aid to the routine diagnosis of nutritional deficiency. For the same reason it is probably wise at present to withhold judgment on the significance of reports based on such procedures concerning the incidence of nutritional night blindness in the community.

THE VITAMIN B COMPLEX

Riboflavin Deficiency

In last year's review² on the water soluble vitamins, reference was made to the fact that although at that time riboflavin deficiency had not been recognized in man, nevertheless riboflavin was probably important in human nutrition, because it had been shown to be the active component ("prosthetic group") of Warburg's yellow enzyme, which apparently plays an extremely important role in the oxidative mechanisms of the tissues. Since the publication of that review clinical evidence of riboflavin deficiency has been obtained.⁵ Eighteen women were fed for a long period on a deficient diet essentially similar to that which is taken by the inhabitants of districts where pellagra is endemic. Thirteen of these women developed characteristic lesions of the mouth and face. The lesions did not respond to nicotinic acid therapy but were cured by the administration of pure synthetic riboflavin. The nature of these lesions is threefold. There is maceration and fissuring at the angles of the mouth, a type of lesion formerly referred to as perleche or angular stomatitis. The mucous membrane at the line of closure of the lips is red and denuded, the name "cheilosis" has been proposed for this lesion. Finally, there is a scaly greasy desquamation in the nasolabial folds, on the alae nasi, in the vestibule of the nose and sometimes on the ears and eyelids. Angular stomatitis had been previously recognized in many parts of the world as a man-

ifestation of deficiency disease. It is commonly present in pellagra and in Oriental beriberi,⁶ and has also been described as occurring in the absence of other evidence of vitamin B complex deficiency. That it occurs in association with deficiency of the vitamin B₂ or heat-stable fraction of the complex had been recognized previously.^{7,8} Further work will have to determine whether these lesions can always be accepted as evidence of riboflavin deficiency. It may turn out eventually that they are merely a nonspecific manifestation of poor nutrition, though readily curable by one particular nutritional factor when lack of this factor is the principal deficiency present.

Though riboflavin has been isolated and synthesized as a yellow crystalline powder, with the formula $C_{17}H_{20}N_4O_6$, it is still an expensive product. For this reason, and also because of their possible non-specificity, perlèche and cheilosis should be treated not with pure riboflavin but with yeast or crude liver extract, which are good sources of riboflavin, and at the same time contain other nutritional factors which may be of value in the particular case concerned.

Vitamin B (Complex) Deficiency

In recent years it has come to be realized with increasing clarity that the syndromes known as beriberi and pellagra are not the result of deficiency of a single dietary factor, but are the clinical consequence of multiple deficiencies involving several components of the vitamin B complex, and sometimes other dietary factors in addition. Moreover, although the classic syndromes of pellagra and beriberi are rarely encountered except in those parts of the world where they are endemic, some of the features of both these syndromes occur, with much more frequency than was formerly realized, in cases seen in other communities.

Deficiency of the vitamin B complex is liable to arise not only from faulty diet but also from defective absorption and from an increase in the nutritional needs of the body. This deficiency therefore is sometimes encountered in patients who can afford an ample and varied diet. In alcohol addicts, for instance, a polyneuritis of nutritional origin may occur, which though often mainly the result of poor eating habits is partly due to the fact that certain components of the vitamin B complex are utilized with unusual rapidity when the caloric consumption (in the form of alcohol) is abnormally high. A similar polyneuritis may occur in pregnancy, often partly as a result of loss of food by repeated vomiting, but also because of the increased nutritional requirements of pregnancy. Defective intestinal absorption is proba-

bly the principal factor in the production of polyneuritis occurring in patients suffering from organic lesions of the gastrointestinal tract. In these various conditions the type of polyneuritis is in every way similar to the polyneuritis of beriberi, and almost certainly has the same fundamental etiology.

The principal clinical manifestations of vitamin B deficiency are enumerated below.

Pellagrous dermatitis. This is mainly due to nicotinic acid deficiency, but, as it occurs on the face, may partly result from riboflavin deficiency (see above). Occasionally another type of dermatitis, due to vitamin A deficiency,^{6,9} may occur in association with vitamin B deficiency, particularly in beriberi.⁶ This is manifested by the presence of hyperkeratotic plugs in the sweat glands, dry skin and absence of sweating. It has been recently claimed¹⁰ that hyperkeratosis of the skin follicles around the nose is due to riboflavin deficiency but this seems doubtful.

Angular stomatitis. This is frequent in many deficiency states. Its relation to riboflavin deficiency has already been discussed.

Glossitis. In endemic pellagra, this is the result of nicotinic acid deficiency, but it is due to other causes in some other nutritional disorders.

Diarrhea and perianal inflammation. This occurs in pellagra, owing to nicotinic acid deficiency.

Polyneuritis. This is frequent in beriberi, pellagra and other nutritional disorders, it is commonly thought to be due to thiamin (vitamin B₁) deficiency.

Degenerative changes in the spinal cord. These occur in severe pellagra and beriberi, they are perhaps due to deficiency of the undefined factor whose deficiency is also responsible for combined system disease associated with pernicious anemia.

Psychosis. This is frequent in pellagra and occasionally occurs in beriberi.⁶ Acute psychosis associated with vitamin B deficiency usually responds dramatically to nicotinic acid therapy. Long-standing pellagrous dementia responds less well and Korsakoff's psychosis probably not at all, indicating the operation of some other factor or the development of irreversible structural changes.

Cardiovascular changes. These include tachycardia, cardiac dilatation, peripheral vasodilatation, edema and tendency to fatal syncope, they are common in beriberi and are probably a direct result of thiamin deficiency, although coexistent protein deficiency and consequent hypoproteinemia may sometimes play a part in the production of edema.

Anemia. This is sometimes severe in deficiency disease in the tropics, and is common in deficiency

associated with alcoholism, it is due to deficiency of some as yet unidentified nutritional factor, possibly identical with the dietary factor, which if not acted on by the intrinsic factor of the stomach leads to pernicious anemia. Anemia occurring in cases of vitamin B deficiency may be due also to other causes.

Porphyria It has been repeatedly stated recently that porphyria is a characteristic feature of pellagra. However, it has been shown^{11, 12} that the test for porphyrin employed in the work on which these statements are based is not a test for porphyrin. It has not yet been proved that porphyria can be caused by pellagra. It does occur in cases of pellagra associated with alcoholism and liver disease, and in such cases is quite probably due to the liver disorder.

Each of the foregoing manifestations is liable to occur in association with one or more of the others in any particular case of vitamin B deficiency, depending on which factors in the complex are chiefly lacking from the diet. The fact that endemic pellagra and beriberi usually present a clear-cut clinical syndrome is probably due to the uniformity of the diet in the locations where they occur. Elsewhere the clinical picture is far more diverse, coincident with a greater variety in the composition of inadequate diets. The multiple causation of the clinical features in most cases of vitamin B deficiency renders it particularly important to treat such cases with some preparation which will supply all the various elements in the complex. Yeast concentrates and crude liver extract are particularly suitable for this purpose. A complete, high caloric diet is also necessary to supply other important dietary essentials which, though usually not sufficiently lacking to produce any definite manifestations, are very frequently taken in insufficient amounts by subjects showing evidence of vitamin B deficiency. The pure synthetic vitamins now available should be considered only as a useful addition to this treatment, for employment in cases where evidence of deficiency of one particular factor is outstanding.

Therapeutic Use of Nicotinic Acid

The conclusions reached last year³ concerning the use of nicotinic acid in the treatment of the outstanding features of pellagra have been confirmed in most respects by subsequent work. The original optimistic report¹³ of its use in the cure of the psychotic symptoms has been somewhat revised. It is now admitted¹⁴ that some cases with long standing mental symptoms respond only partially to nicotinic acid therapy. As pointed out above, some part of the dermatitis in pellagra

may be due to riboflavin and vitamin A deficiency, and therefore will not be affected by nicotinic acid therapy. A report¹⁵ based on a careful study of the use of nicotinic acid in the treatment of pellagra indicates that 200 to 300 mg per day taken by mouth is a suitable therapeutic dose. The opinion of one experienced observer¹⁶ concerning the use of nicotinic acid is "enthusiastic, but not quite as enthusiastic as are many others about the value of the drug."

The Therapeutic Use of Thiamin

Despite the numerous statements in the recent literature that nutritional polyneuritis is due to deficiency of thiamin, I still believe that the evidence on which these statements are founded is not sufficient to justify the treatment of an uncomplicated case of nutritional polyneuritis with thiamin only. Although additional thiamin may be beneficial, adequate treatment should include an ample and nutritious diet, together with some preparation of yeast or crude liver extract.

ASCORBIC ACID (VITAMIN C)

There is little new knowledge concerning vitamin C. The successful use of an injectable form of the vitamin has been reported.¹⁷ An excellent review of present-day knowledge regarding the diagnosis of vitamin C deficiency and the therapeutic use of ascorbic acid will be found elsewhere.¹⁸

VITAMIN D

Dihydroxycholesterol (A.T. 10) has been successfully used in the treatment of hypoparathyroidism. This substance is very closely related chemically to vitamin D and has some of the same biological properties. It facilitates the absorption of calcium from the intestines, but has a more marked effect than does vitamin D in increasing the urinary excretion of phosphorus, which is probably the reason why it is not effective in rickets.¹⁹ These properties make it peculiarly suitable for the treatment of hypoparathyroidism. It has been pointed out²⁰ that a patient with hypoparathyroidism may take A.T. 10 in much the same way as insulin is taken by patients with diabetes, the dose being controlled by a simple test for calcium in the urine.

VITAMIN K

Knowledge concerning vitamin K has advanced with extraordinary rapidity during the last year. This knowledge is certainly the most outstanding achievement of nutritional science since the discovery of the pellagra preventing activity of nic

otinic acid two years ago. No attempt can be made here to review all the recent literature on vitamin K. The following account is confined to a brief summary of the present status of this vitamin. For a more complete account the reader is referred to two very helpful reviews^{21, 22} which have appeared during the last year.

Chemistry

Following the successful isolation of vitamin K by several independent groups of workers,²³⁻²⁶ recognition of its chemical composition soon followed. It was found to be related chemically to the substance phthiocol, which had been previously isolated from tubercle bacilli²⁸ and has now been shown to possess vitamin K activity.²⁷ As in the case of vitamin D, it is realized that vitamin K is not a single chemical entity, and that several closely related compounds possess vitamin K activity. They are all related chemically to naphthoquinone. Natural vitamin K₁ obtained from alfalfa has a slightly different chemical composition than has vitamin K₂ isolated from putrefied fish meal.²⁸ Vitamin K₁ has now been synthesized.^{29, 30} At the present time it appears³¹ that 2-methyl-1, 4-naphthoquinone is the most active of the synthetic compounds so far studied. The relative simplicity of these active synthetic compounds should enable them to be manufactured on a considerable scale, and before long they will doubtless be freely available for general use.

Physiology

Vitamin K was first recognized in 1935 from the fact that chickens fed on a diet deficient in this vitamin developed hemorrhages. The bleeding was apparently due to a fall in the concentration of prothrombin in the blood. According to the Howell theory of blood coagulation, prothrombin is the substance which in the presence of calcium and thromboplastin yields the active substance thrombin. Thrombin then converts fibrinogen to fibrin, thus bringing about coagulation. It is now believed that vitamin K is essential for the normal synthesis of prothrombin in the body, and perhaps is actually the active component (or "prosthetic group") of this substance. Apparently the liver plays a very important part in this synthesis.³² Vitamin K, like other fat-soluble substances, requires the presence of bile salts to facilitate its absorption from the intestinal tract.³³ It is probably present in many common foodstuffs. The vitamin is produced by other bacteria besides the tubercle bacillus, including those present in the intestines, and these may provide an important source of the vitamin.

Human Pathology

Vitamin K deficiency and consequent hypoprothrombinemia may result from inadequate intake or from defective intestinal absorption. In addition, hypoprothrombinemia may occur as a result of failure of the liver to utilize vitamin K in the synthesis of prothrombin.

Inadequate intake It has been shown³⁴ very recently that adult individuals partaking of an inadequate diet may show a reduced concentration of prothrombin in the blood, and that the administration of vitamin K will correct this abnormality. It has also been shown that in newborn infants,^{35, 36} and perhaps particularly in premature infants,³⁷ there may be a similar reduction in the level of prothrombin in the blood which usually responds to the administration of vitamin K. It has been suggested that this deficiency is due at least in part to delay in establishing in the bowel the normal bacterial flora which is able to synthesize the vitamin.³⁸ This discovery is obviously of the greatest importance in relation to hemorrhagic phenomena in the newborn, and it seems likely that administration of vitamin K to the mother prior to delivery might materially lessen the incidence of intracranial bleeding and other types of hemorrhage in the newborn.³⁷

Defective absorption In the absence of an adequate secretion of bile, vitamin K absorption is impaired and hypoprothrombinemia is liable to result. It now appears³⁹ that this is the explanation of the bleeding that occurs in cases of obstructive jaundice, and that has been responsible in the past for nearly a fifth of the operative deaths in the surgical treatment of patients with jaundice. It has been clearly demonstrated by several groups of workers⁴⁰⁻⁴² that in most cases of obstructive jaundice with bleeding tendency, the oral administration of vitamin K together with bile salts is effective in increasing the prothrombin level in the blood and in checking the hemorrhage. Vitamin K deficiency conditioned by defective intestinal absorption may also occur as a result of intestinal obstruction, surgical short circuits and certain disorders associated with diarrhea, such as ulcerative colitis and sprue.⁴³

Defective prothrombin synthesis It appears that in certain primary diseases of the liver the synthesis of prothrombin may be impaired, despite an adequate intake of vitamin K. In these conditions administration of vitamin K is less likely to be successful in raising the prothrombin level of the blood and preventing hemorrhage.⁴⁰

Diagnosis

At the present time there is no method of meas-

uring directly the amount of prothrombin in the blood, but an indication of this amount can be obtained by measuring in the test tube the time taken for the blood or plasma to clot, after precautions have been taken to see that all other substances necessary for clotting are present in excess and that the amount of prothrombin is therefore the only limiting factor. In practice the method of Quick⁴⁴ appears to be the most convenient and reliable for ordinary clinical purposes. The only practical difficulty in the use of such tests as a routine laboratory procedure is that of obtaining a satisfactory source of thromboplastin to ensure an adequate concentration of this substance in the material to be tested. It is probable however, that before long some stable preparation of thromboplastin will be found. The method will then become a simple matter that can be carried out in any routine laboratory. One difficulty in interpreting the significance of prothrombin times is that the time does not become significantly prolonged until the level of prothrombin in the blood has fallen considerably, perhaps almost reaching the point at which hemorrhagic phenomena are liable to appear. For this reason the demonstration of a normal prothrombin time in a case of jaundice prior to surgical operation is no guarantee against a dangerously low level of prothrombin in the blood, and is certainly no insurance against postoperative hemorrhage. Lesser degrees of hypoprothrombinemia can be demonstrated if necessary by diluting the plasma with additional plasma rendered free from prothrombin⁴⁵ the consequent reduction in prothrombin concentration may demonstrate a deficiency of prothrombin in specimens which, undiluted, show a normal prothrombin time.

Treatment

At the present time the indications for the administration of vitamin K as a prophylactic measure appear to be as follows. It should be given to expectant mothers shortly before delivery. Its use is indicated in cases of intestinal obstruction surgical short circuits of the intestines and conditions associated with chronic diarrhea. It is worthy of trial in chronic liver disease, but is particularly valuable in the preoperative and postoperative treatment of cases with obstruction of the common bile duct.

Vitamin K is of the greatest value in the treatment of hemorrhagic disease of the newborn, and in bleeding associated with obstructive jaundice. It will probably be found effective in cases of bleeding associated with disorders of the alimentary tract when ascorbic acid deficiency is not the

cause. It should be tried in bleeding associated with primary diseases of the liver. It is almost certainly not effective in hemorrhagic conditions such as hemophilia and purpura hemorrhagica.

Methods of Administration and Dosage

Oral administration is usually effective. In cases where the secretion of bile is impaired, bile salts in capsules (2 to 4 gm.) should be given together with the vitamin. When the bleeding is severe and the condition urgent, administration by duodenal tube has been recommended.⁴⁶ Some preparations of vitamin K can also be given parenterally the efficacy of this route of administration is at present undergoing trial.

No recommendation as to dosage will be made in this review, since the advent of synthetic vitamin K has rendered obsolete all previous reference to doses in terms of arbitrary standard units. Units defined in terms of pure synthetic vitamin will probably be adopted very shortly, and until that time the reader will find adequate recommendations elsewhere² as to appropriate doses in terms of the units at present employed.

**CASE RECORDS OF THE
MASSACHUSETTS GENERAL HOSPITAL**ANTEMORTEM AND POSTMORTEM RECORDS AS USED
IN WEEKLY CLINICOPATHOLOGICAL EXERCISES

FOUNDED BY RICHARD C. CABOT

TRACY B. MALLORY, M.D., *Editor***CASE 26081****PRESENTATION OF CASE**

A fifty five year-old Italian woman was admitted to the hospital complaining of pain in the right flank.

Two years before admission the patient developed polydipsia and polyuria, and a diagnosis of diabetes mellitus was made in an outside dispensary. Since that time a daughter had tested her mother's urine at least twice a week, and had given her insulin according to the test. Further information regarding the diabetes was not obtainable.

The patient was allegedly well until seven days before entry when she noticed a "ticking" sensation about the urethral meatus during urination, associated with frequency and nocturia. Four days before admission she developed a constant steady pain, located in the right flank and right costovertebral area, which occasionally radiated downward into the right groin, this aching discomfort persisted until admission. She also developed a slight nonproductive hacking cough, which at times made her flank pain more severe. No chills, fever or other genitourinary, cardio-respiratory or neuromuscular symptoms were noted. The patient had been pregnant twenty seven times. Eight children had died in infancy, and there had been ten miscarriages. The menopause had occurred four years before admission. The remaining family, marital and past histories were negative.

The physical examination revealed a corpulent, flushed woman who lay flat in bed, moaning and groaning. Her respirations were rapid and shallow. Examination of the heart, lungs, abdomen and extremities was negative. There was an erythematous moist rash about the pubic region. The pelvic and rectal examinations were negative. The blood pressure was 110 systolic, 70 diastolic.

The temperature was 102.4°F., the pulse 90, and the respirations 32.

Examination of the blood showed a red-cell count of 5,050,000 with 85 per cent hemoglobin, a white-cell count of 15,400 with 84 per cent polymorphonuclears, and a normal smear. The urine was slightly turbid and had a pH of 5, a specific gravity of 1.020 and a ++ albumin test, in the sugar test it was green with a yellow sedi-

ment, acetone and diacetic acid were absent. The sediment was negative for red cells, but contained innumerable clumps of white blood cells and a few coarse granular casts. Abundant colon bacilli were cultured from the specimen. The stools were brown, soft, formed and guaiac negative. The blood Hinton test was negative. The admission blood sugar was 640 mg per 100 cc., the carbon-dioxide combining power 24 cc. N/10 carbonic acid, and the nonprotein nitrogen 63 mg. A blood culture showed no growth. Serum Widal and undulant fever agglutination tests were negative.

Roentgenograms of the lumbar spine and pelvis showed lipping along the articular margins consistent with a moderate degree of hypertrophic arthritis. The large bowel contained a moderate amount of gas and fecal material. No grossly dilated intestinal loops were visible. Films of the chest showed that the diaphragms and lower lung fields were obscured by large breasts. The lung fields were clear so far as they were shown on the films. Maximum x-ray exposure did not succeed in outlining the bases. The heart was within the upper limits of normal. Retrograde pyelograms showed a normal kidney pelvis and ureter on the left side. The greater portion of the right kidney pelvis was filled and appeared normal.

The patient remained in the hospital twenty nine days, during which time, for the first two weeks, she ran a constantly elevated but spiking fever, ranging daily from 101 to 102.6°F. The pulse varied similarly from 90 to 120, and the respirations were elevated between 30 and 45. For the last two weeks the temperature spiked more widely, and gradually rose to 105°F. before her demise, the pulse and respirations rose to 140 and 50 respectively.

She was placed on a diabetic dietary regime and was given insulin, and in three days after admission the blood sugar was 272 mg per 100 cc. It was maintained around this figure for the remainder of her illness, on one occasion, two weeks after entry, it was 155 mg. She was maintained thus on approximately 30 units of insulin a day. The urine sugar tests were green with sediment or blue, and the diacetic and acetone tests were all negative.

Because of the patient's urinary infection, sulfanilamide was administered to a blood level of 6.6 mg per 100 cc. on the eighth hospital day. The red-cell count on the tenth day was 3,170,000 with 62 per cent hemoglobin, and the white-cell count 18,000. The patient failed to respond, the urine continued to show abundant colon bacilli, and the pyrexia persisted. On the eleventh day the sulfanilamide blood level was 9.5 mg per 100 cc. On the thirteenth hospital day the red-cell count had

fallen to 2,700,000, and the leukocytes were 11,400. Sulfapyridine was substituted for sulfanilamide for the next four days. On the fourteenth day the patient received a 500-cc transfusion, and during the next fourteen days three similar transfusions were administered. From the eighteenth to the twenty-seventh hospital day sulfanilamide was again given to the patient, 10 gm four times a day. The red-cell and white-cell counts fell slowly and steadily, in spite of transfusions, to 2,490,000 and 7300 respectively on the twenty-fourth hospital day. On the twenty-fifth day a van den Bergh was 20 mg per 100 cc, biphasic, a bromsulfalein test gave 50 per cent retention of the dye, the carbon-dioxide combining power and serum chlorides were within normal limits. On the twenty-eighth day the red cells were 1,640,000, the white cells 400. The smear showed a few lymphocytes but no granulocytes. The patient became delirious, developed Cheyne-Stokes respirations, failed and died on the next day.

DIFFERENTIAL DIAGNOSIS

DR CHARLES L. SHORT: May I see the x-ray films?

DR GEORGE W. HOLMES: I do not believe I can add anything to the description given in the text. Certainly the diaphragm is high. She was a large heavy woman, apparently, and the poor aeration could be explained the way it was in the report. There is nothing characteristic about the chest films. Those of the pelvis, taken after the retrograde injection was made, are not complete, but I do not see anything characteristic about them. I should think they would be interpreted as negative.

DR SHORT: I think we can accept the diagnosis of diabetes in this patient without question. She was undoubtedly a mild case in a middle-aged individual who had a high threshold for sugar, perhaps due in part to renal infection with diminished renal function. Further evidence that it was a mild case is the fact that she developed no acidosis in spite of the infection. During the course of the patient's illness the diabetes was well controlled, and I do not believe we can say that it bore any direct relation to her death.

We can also accept the diagnosis of urinary infection due to the colon bacillus, presumably with pyelitis and pyelonephritis. There is no evidence from the pyelograms or clinically of any urinary obstruction, but with twenty-seven pregnancies she may well have had a cystocele that contributed.

The patient was treated with sulfanilamide. That was started on the eighth hospital day and on the tenth the red-cell count was 2,000,000 lower than

on admission. It would be interesting to know what the count was the day before sulfanilamide was started—in other words, whether this was a fall over two days or whether the count had been falling steadily because of her infection. The days later there was noted a further fall in the red-cell count to below 3,000,000. At this point sulfapyridine was substituted for three days, either because of the anemia the patient was developing or possibly because the infection was not being controlled by the sulfanilamide. From that time on the patient was given sulfanilamide until ten days before her death. She had four transfusions but the red-cell count remained level for a while and finally fell off still more. Then she developed jaundice, with a positive van den Bergh test, and died with a red-cell count of 1,600,000 and agranulocytosis.

The question that must be decided at the outset is whether the anemia or agranulocytosis could have been due to anything besides drug toxicity. I think we must assume that the blood changes were due to the sulfanilamide and sulfapyridine rather than to the infection, but of course in a patient with severe infection and receiving sulfanilamide that point cannot be definitely settled at a mortem. The jaundice I should rather ascribe to the hemolytic type of anemia that characteristic occurs after sulfanilamide than to any form of liver damage secondary to the infection. A depressed liver function is observed in cases of severe hemolytic anemia associated with sulfanilamide, probably due to anoxia of the liver cells. The diphasic van den Bergh is also compatible with a hemolytic anemia and does not predict primary liver damage. It would be helpful to know what the blood smears showed during the course of the disease—as to whether there was any reticulocytosis or other evidence of regeneration, also, whether there was urobilinogen in the urine.

The continued fever toward the end may well have been due to drug toxicity rather than to the original infection, but there is no way of proving that, and it is often a difficult decision to make in a patient who is receiving sulfanilamide. An aplastic form of anemia does rarely occur with sulfanilamide and that is a possibility here, since we do not know whether the blood smears showed aplasia or regeneration, but it certainly is very uncommon, the hemolytic type of anemia being much more frequent.

What would be the autopsy findings which would prove whether my ideas are correct? I think that, if the patient died from a hemolytic anemia due to sulfanilamide, we should find a

hyperplastic bone marrow so far as the red-cell series is concerned and, in addition, evidence of arrested maturation of the white-cell series. This is usually found in cases of agranulocytosis due to drugs, and from the few cases that have been autopsied, sulfanilamide is no exception. In other words, the bone marrow will not show a complete depression of the white-cell series but only an arrested maturation, with mostly blast cells. In addition, the hemolytic nature of the anemia should be evidenced by the deposition of iron-containing pigment in the reticuloendothelial system in the liver and spleen. That would be my explanation as to the cause of her death—that it was largely due to toxicity from sulfanilamide rather than primarily to the urinary infection or to the diabetes.

DR. MAURICE FREMONT SMITH I am interested in the low liver function. Do you usually get that with secondary anemia from any cause?

DR. TRACEY B. MALLORY Not so low as that.

DR. SHORT Low liver function has been reported in cases of severe hemolytic anemia due to sulfanilamide.

DR. WYMAN RICHARDSON I predict that some day we shall see toxic hepatitis from sulfanilamide.

DR. SHORT Toxic hepatitis has been described as due to sulfanilamide, but in this case I should think it was bringing in an extra factor that is not necessary.

CLINICAL DIAGNOSES

Toxic hepatitis.
Diabetes mellitus.
Bacillus coli pyelitis.
Agranulocytosis.

DR. SHORT'S DIAGNOSES

Pyelonephritis.
Hemolytic anemia.
Agranulocytosis.
Diabetes mellitus.

ANATOMICAL DIAGNOSES

Chronic pyelonephritis, bilateral.
Perinephric abscess, right.
Cystitis, acute hemorrhagic.
Obesity.
Agranulocytosis.
Erythropoietic hyperplasia.

PATHOLOGICAL DISCUSSION

DR. MALLORY The autopsy on this woman showed that there was an extremely severe bilateral pyelonephritis with multiple abscesses scattered throughout both kidneys, and on the right side one of these had perforated the capsule and

a perinephritic abscess had developed anterior to the kidney, lying between the adrenal gland and the second portion of the duodenum. It was a rather extensive pencil-like tract, which was not very wide at any point. There was nothing in the clinical history that suggested it at all. I do not believe that anyone could have localized it or drained it.

The other finding of major interest was the condition of the bone marrow. That showed a definite hyperplasia of the red-cell series, which had extended even into the long bones. The marrow in the central part of the femur was quite markedly erythrogenic. There were a moderate number of undifferentiated cells, but most of them appeared to belong to the red-cell series, so far as we could identify them. The white-cell elements appeared to be completely and specifically eliminated. Megakaryocytes were present in normal numbers, and a moderate number of plasma cells were found. Whether on that basis we can decide that this agranulocytosis was or was not due to sulfanilamide, as Dr. Short suggests, I am uncertain, but my inclination is to believe that it primarily was.

DR. JAMES H. THORNDIKE Did she have a fatal lesion in the kidneys?

DR. MALLORY Yes, I think there is not the slightest doubt that she would have died of renal sepsis.

DR. EUGENE S. SULLIVAN Do you remember whether the abscesses in the kidneys showed polymorphonuclears?

DR. MALLORY None whatever. Cultures from them showed *Bacillus coli* and nonhemolytic streptococci.

DR. RICHARDSON How about the liver?

DR. MALLORY It showed essentially nothing. There was a good deal of hemosiderin in the bone marrow and spleen.

DR. SHORT What is the possibility that there were blasts completely undifferentiated, but be- longing to the white-cell series, in the bone marrow?

DR. MALLORY The total cellularity of the bone marrow was about half normal, and the half that you could identify appeared to be wholly of the red-cell series.

DR. SHORT Has that been your observation in the cases of agranulocytosis—arrested maturation rather than aplasia of the white-cell series?

DR. MALLORY Usually, but I am sure I have seen both types of reaction.

I do not believe the autopsy findings can be considered conclusive one way or the other. I certainly do not believe that I can exclude the possibility that the agranulocytosis was due to the

sulfanilamide. On the other hand the amount of renal sepsis was, I am sure, enough to have been lethal, strenuous efforts were therefore justified in the attempt to control it

CASE 26082

PRESENTATION OF CASE

A sixty-four-year-old widowed Canadian nurse entered the hospital complaining of asthma.

Approximately three weeks before entry the patient had a chest cold associated with a slight cough, more pronounced at night, with the production of white, frothy, stringy, tenacious sputum. One week later she suddenly had an attack of difficulty in getting her breath both on expiration and inspiration, although this was seemingly more marked with the latter. A physician was called, and he gave her adrenalin, which relieved her. After that she had occasional similar but less severe attacks, which were controlled by capsules left by her physician. She was also taking an expectorant cough medicine at that time. She had a severe attack one week before entry, and another on the evening before entry which was so bad that she "nearly died" and required adrenalin. She had had two attacks of asthma during her life, both very slight. The first attack, thirty years before admission, was associated with smoke from stove polish, and the other, twenty-five years before entry, was without any known cause. She had lived in the same house for two years and had had a dog for ten years. She had always noted that she felt much better when at a high altitude. For the previous seven years during the month of August she had had hay fever. This was always relieved by going to Nova Scotia. She had never had any skin lesions and was not subject to food idiosyncrasies.

There was no family history of hay fever or asthma. She had been born in Nova Scotia, and all her life had been spent either there or in Massachusetts, except for several years in California. There was no history of pneumonia or pleurisy.

Physical examination showed a well-developed and rather thin woman in no apparent distress. The chest showed slight hyperresonance and was clear except for occasional diffuse squeaks and groans. The heart was not enlarged, the sounds were not remarkable. No murmurs were heard. There was slight accentuation of the apical first sound. The blood pressure was 165 systolic, 80 diastolic. The peripheral arteries were firm.

The temperature was 98°F, the pulse 82, and the respirations 22.

Examination of the urine was negative. The

blood showed a red-cell count of 6,180,000, a hemoglobin of 80 per cent, and a white-cell of 10,300 with 60 per cent polymorphonuclear cells, 28 per cent lymphocytes, 8 per cent monocytes and 4 per cent eosinophils. The sputum was and mucoid and contained a few cocci in blood. The stools were negative.

X-ray films of the chest showed diffuse clearing of the lung markings, without any consolidation. The diaphragm was low in position and limited in excursion. A sinus showed diffuse thickening of the lining membrane of all sinuses, with obliteration of the cavities of the right ethmoids.

She continued to raise mucopurulent sputum. Adrenalin helped her a great deal, although the chest still had scattered sibilant rales. Intradermal tests showed a good-sized reaction to ragweed, smaller ones to grasses. The tests somewhat aggravated her asthma, but this was slowly relieved by adrenalin. During the evening of the day she had a severe asthmatic attack. Her pulse was weak and rapid, cyanosis was marked, there was no relief from adrenalin. She was put in an oxygen tent, with improvement. The extremities were cold and cyanotic. Intravenous 1 per cent glucose, containing 1 cc of adrenalin, gave no striking relief. The blood pressure fell to 70 systolic, 70 diastolic, and the pulse was 120. She rapidly failed and died the following evening.

DIFFERENTIAL DIAGNOSIS

DR MILTON H. CLIFFORD. The story on reading seems to be consistent with a perfectly clear-cut case of a woman dying in status asthmaticus, without any complicating factors. In fact, the sounds altogether too direct a story to be such a diagnosis.

Here is a woman who, so far as we know, has been perfectly healthy until the last month of her life, except that at intermittent times she had allergic manifestations—many years ago in the form of asthma, and in the last seven years in the form of hay fever—which one gathers have been severe enough to bring her to a physician. We do not know whether her present hospitalization was during the time of the hay-fever season; if so, one would, perforce, be pushed even further to the diagnosis of asthma. Moreover, an attack of asthma is not uncommonly precipitated by an upper-respiratory infection. Thus the history is entirely in favor of asthma.

The physical examination also seems to confirm this, in that it was essentially negative except for the hyperresonance of emphysema and the occasional squeaks and groans. It is to be noted, however, that when she was seen at home there were

to be even more difficulty in inspiration than in expiration, contrary to what one usually expects. The examination of the heart is reported as essentially negative, accentuation of the first sound means little, and it would be impossible to read a story of mitral stenosis into such minimal findings. There is no mention of distention of the neck veins, of engorgement of the liver or of the inability of the patient to lie flat. One assumes, however, the absence, particularly of the last observation, means that she was not having cardiac orthopnea. Further, the temperature was normal, and so far as we know, it stayed at least essentially normal throughout her stay, a fact which is against a complicating infection.

The x-ray films of the lungs give negative confirmation, particularly helping to rule out the possibility of a foreign body or of a tumor in the mediastinal region. The sinus film was quite consistent with an allergic state, presumably with thickened membranes and, along with the normal white-cell count and temperature, with no active infection. Probably a nasal examination would have shown a vasomotor rhinitis.

The most interesting of the laboratory findings is the polycythemia, which is perfectly consistent with the pseudopolycythemia seen in asthma, although whether associated with dehydration or with compensatory increase in oxygen-carrying units, particularly in view of a comparatively low hemoglobin, I do not know. The blood smear does not help us much, except that the eosinophilia of 4 per cent is consistent with, if not lower than what is often found. Again, the paucity of organisms in the sputum goes with the thick, mucoid, plugging secretion found in the asthmatic patient.

In considering other types of illness, diffuse thickening of the lung margin is suggestive of a much longer process than the story which we have, and could go with a mild degree of non-specific pulmonary fibrosis or with bronchiolitis obliterans. But a fatal degree of these would be unlikely with so short a history, at least without more suggestive evidence of a cor pulmonale and a more prolonged and febrile terminal stage. Furthermore, no mention is made of clubbed fingers to go with a chronic pulmonary condition.

A foreign body in the main bronchus is not ruled out, except that the sputum was at no time either purulent or bloody, nor were there definite areas of atelectasis. What plugging there was apparently must have been with spasm and possibly related mucous plugs. Friedländer's bacillus will cause a very thick tenacious sputum, but again the patient had no febrile course, and except for

the short terminal stage, was apparently not unduly sick.

There is one other possibility. We presume that this woman had some hypertension with a systolic pressure of 165 at entry. We also are led to the assumption that she had at least some generalized arteriosclerosis, as noted in the firmness of the radial arteries. Could it be possible that during the severe asthmatic attacks, on the tenth day, she had a coronary infarction? Certainly this can occur without pain, and with marked dyspnea. One would think, however, that such dyspnea would be out of proportion to the squeaks and groans heard in the chest. The blood pressure fell, but this could have been due to shock in any situation and not at all specifically to a coronary infarction. Cyanosis could have gone with either. One might expect varying irregularities of the heart rate or a suggestion of cardiac enlargement with an infarction. These would not be necessary, however, and no remark on the pulse, except its rapidity, is noted. I do not believe that this possibility can be either ruled in or out. An electrocardiogram might possibly have helped a great deal. The amount of peripheral shock she was in could have been present with status asthmaticus as well as with coronary infarction.

There is no mention as to whether she was given any of the opium derivatives before or during this stage of shock. To many of the asthmatic patients, particularly those with symptoms as severe as those this woman had morphine or pantopon seems to be an aggravator or instigator of even more severe asthma. Thus, even if it were known that she had a coronary occlusion unless it had been previously ascertained she was not sensitive to opium derivatives, it would not have been wise to use them.

We have repeatedly heard that patients do not die in an asthmatic attack. Several years ago Dr. Mallory told me that he had seen some 13 cases in the Massachusetts General Hospital, up to that time who had died of no other findable cause than the bronchial spasm of asthma and the lungs distended with trapped air.

My belief is that this patient died of bronchial asthma, that she had some arteriosclerosis, and by guesswork only, that she did not have any coronary infarction.

CLINICAL DIAGNOSES

Bronchial asthma
Chronic bronchitis
Emphysema.
Terminal pneumonia

DR CLIFFORD'S DIAGNOSES

Status asthmaticus
Emphysema of lungs
Arteriosclerosis, general

ANATOMICAL DIAGNOSES

Bronchial asthma
Pyelitis, bilateral, moderate
Cholelithiasis
Arteriosclerosis, slight, aortic
Leiomyomas of the uterus
Pleuritis, chronic fibrous, left

PATHOLOGICAL DISCUSSION

DR TRACY B MALLORY As Dr Clifford has already intimated we have had in this hospital a considerable experience with fatal bronchial asthma. A significant number of cases die in and apparently of an asthmatic paroxysm. Other modes of death indirectly attributable to asthma are those from cor pulmonale and from emphysema or a combination of the two. It has been our experience that patients with very chronic persistent asthma of twenty or thirty years' duration rarely die in a paroxysm. Paroxysmal deaths are much more frequent in people who have

had comparatively little preceding asthma and especially in people who develop asthma for the first time in their fifties and sixties. Although this woman had had apparently two widely separated single attacks of asthma earlier in her life, it is probably fair to class her in the latter category.

At autopsy the findings were entirely typical of a paroxysmal death. Like all the other cases the bronchial tree from the first subdivision of the primary bronchi down to the respiratory bronchioles was plugged with thick tenacious mucinous casts. The alveoli were uniformly distended to the maximal inspiratory degree, but there was no anatomic fusion of alveoli or other evidence of structural emphysema. The heart, despite the systolic blood pressure reading of 165, was quite small, weighing only 225 gm. It seems doubtful, therefore, if she could have had a significant degree of hypertension, and it is possible that the blood pressure reading was taken shortly after she had received adrenalin. There was certainly no cor pulmonale, since the right ventricle measured only 2 mm in thickness. The coronary arteries were entirely negative. The only coincidental findings of any significance were a slight acute bilateral pyelitis and a stone in the gall bladder.

THE BENZOL HAZARD

The industrial hazards of benzol have long been recognized and in recent years increasingly stringent precautions have been taken to minimize or prevent its untoward effects. Yet, from recent studies, it is distressingly apparent that the potential dangers of this chemical are not appreciated to the fullest extent and that the clinical and pathologic manifestations of benzol poisoning are by no means as simple and clear cut as they were once thought to be.

A provocative series of articles* in the *Journal of Industrial Hygiene and Toxicology* has brought to light a number of previously unsuspected facts. It has hitherto been the general consensus that

Benzene (Benzol) Poisoning: Five papers. Reprinted from the *Journal of Industrial Hygiene and Toxicology* 1939 (21:321-435 1939) 114 pp. BOSTON: Journal of Industrial Hygiene and Toxicology 1939. Bound reprints of three papers in this series, "Chronic Exposure to Benzene (Benzol). I. The Industrial Aspects. II. The Clinical Effects. IV. The Pathological Results," are available for distribution to Massachusetts physicians on application to the Division of Occupational Hygiene, Department of Labor and Industries, 23 Joy Street, Boston.

chronic benzol poisoning was characterized by the syndrome of aplastic anemia, that its earliest manifestation was a moderate or severe leukopenia and that a vapor concentration of 100 parts per million was compatible with complete safety for the workers. In view of the recent studies referred to, some if not all these dicta must be discarded.

It would appear that, in certain cases at least, vapor concentrations of less than 25 parts per million were followed by death, and the authors state that it is doubtful whether any concentration of benzol greater than zero is safe over a long period of time. It is therefore obvious that if benzol is to be used in industry, close medical supervision of all workers is of the utmost importance, and it is to be hoped that in the future an adequate substitute will be developed for this hazardous, though efficient, solvent.

Contrary to what is usually taught, the syndrome of aplastic anemia with its attendant leukopenia is not characteristic of benzol poisoning. Hunter and his associates found in their cases polycythemia and anemia, leukopenia and leukocytosis, leukemoid blood pictures and apparently even true leukemia. Regarding the last, Mallory states "The evidence that chronic exposure to benzene produces leukemia in human beings is still incomplete, but it is accumulating at a rate and to a volume which command serious consideration."

It is further stated that the clinical symptoms and signs of chronic poisoning may appear after a prolonged latent period, during which the worker may not have been exposed to the chemical and it is suggested that under certain circumstances industrial compensation must be extended to include cases of poisoning long after exposure has ceased. It is well to remember, however, that the *post hoc ergo propter hoc* argument has been and always will be uncertain and that one should not be too hasty in attributing a given hematologic disorder to an exposure to benzol some years before.

One can no longer rely on leukopenia as the earliest sign of benzol poisoning, and the bone marrow may apparently be aplastic, hyperplastic,

leukemoid or even deceptively similar to "the neoplastic processes termed Hodgkin's sarcoma"

According to Hunter's findings, benzol poisoning must be suspected whenever, in an exposed person, an eosinophilia exists, whenever the percentage of polymorphonuclear neutrophils is decreased or whenever young white blood cells are present in the peripheral blood, and the earliest diagnosis must depend on an evaluation of the complete blood picture rather than any particular hematologic feature. The diagnosis must be made, or at least suspected, before anemia develops, if a favorable outcome is to be expected.

It is clear that the former criteria for the clinical and pathological diagnosis of benzol poisoning must be revised. It would appear that a large variety of hematologic syndromes may follow exposure to benzol, even in minimal concentrations. The clinical and industrial implications of these facts are far-reaching and of the greatest importance.

A GOVERNMENTAL SYPHILIS PROJECT

A LETTER in this issue of the *Journal* calls attention to a governmental activity in the field of medicine which has been going on in Boston since 1937. The syphilis problem is large enough to demand a careful investigation from every possible angle. The best results can be obtained by the co-operation of all possible organizations in a particular region. It is quite necessary that any such survey be undertaken by individuals with adequate experience in syphilis and in the interpretation of the records of such cases. In the case of the records themselves, there are undoubtedly periods in any hospital when the records are not accurate, perhaps by reason of insufficient personnel or by reason of changes or additions to personnel, particularly that brought about by new individuals coming into the hospital for training.

Any such survey should be under the careful direction of the hospital staff in addition to the personnel of the project, because the members of the former are usually much more familiar with

the patients and problems of the clinic. Such co-operative studies of the end results of syphilis, carried on with definite assurance of proper supervision and of a satisfactory technic for developing the desired statistics, should furnish considerable information with regard to the status of syphilis in a particular community.

MEDICAL EPONYM

BASEDOW'S DISEASE

The description of exophthalmic goiter which is considered classic by the Germans is that of Karl A. von Basedow (1799-1854), a practicing physician in Merseburg. It appeared in Casper's *Wochenschrift für die gesammte Heilkunde* (197-204, 220-228, 1840). The article is entitled "Exophthalmos durch Hypertrophie des Zellgewebes in der Augenhöhle [Exophthalmos as a Result of Hypertrophy of the Cellular Tissue of the Orbit]." The translation of a portion of the article is as follows:

I have frequently observed exophthalmos caused by a diseased condition of the cellular tissue of the orbit—a peculiar hypertrophy which seemed to arise as the result of disease of the heart and the larger blood vessels of certain glandular and other tissues.

Fourteen years ago I first made the acquaintance of Mrs. G., when she was a nineteen-year-old girl. At that time she was still suffering from scrofulous glands in the neck, but was otherwise well. She had had an acute rheumatism which had left, as sequelae, edema of the ankles, loss of weight, amenorrhea, palpitation and rapid small pulse, precordial distress and dyspnea. Even at this time there was also, however, a definite protrusion of the otherwise healthy and visually normal eyeball, so that the patient slept with the eyes open, had a frightened appearance, conducted her self in a careless and lively manner, and soon had the reputation of being a little mad.

Coincident strumous swelling of the thyroid gland led me to suspect a similar intumescence of the cellular tissue behind the optic bulb and suggested the use of iodine and digitalis, whereupon an improvement in all her symptoms resulted, although she still showed an unhealthy pallor and her eyes were unnaturally wide open and prominent.

After detailing the typical symptoms of hyperthyroidism in four other cases, he concludes:

Having given it as my opinion that the immediate cause of exophthalmos is a strumous hypertrophy of the cellular retrobulbar tissue, I wish to amplify this by saying that I regard this hypertrophy as an incidental phenomenon, secondary to an abnormal condition of the circulatory system—a blood dyscrasia which, by reason of some as yet unknown scrofulous taint, takes the form of glandular growths and tissue hypertrophy.

SEPSIS DEVELOPING FIVE DAYS
AFTER FORCEPS DELIVERY

Mrs. L. P., a twenty-one year-old primipara, was admitted to the hospital February 13, 1933. She was at term but not in labor, and entered because of a slight bloody show.

The family history was negative, as was the patient's previous history. Catamenia began at fourteen, were regular with a twenty-eight-day cycle and lasted four days. The last period had begun on May 4, 1932, and confinement was expected about February 11.

The pregnancy had been characterized by much nausea during the first trimester. The blood pressure and urine had been consistently negative, and there had been no headaches or edema.

Examination on admission showed a well developed and nourished woman. The temperature was 98.0°F., the pulse 88, the respirations 22, and the blood pressure 120 systolic, 80 diastolic. The heart sounds were clear, and the action regular, there were no murmurs. The lungs showed uniform resonance and were clear. The abdomen presented a full term pregnancy, the fetus lying in an OLA position, with the head well engaged. The pelvic measurements were within normal limits.

Rectal examination showed no dilatation of the cervix. There was a slight discharge of blood tinged mucus. Urine examination showed the slightest possible trace of albumin and no sugar. The sediment was essentially negative. A blood Wassermann test was negative.

After a twelve hour labor the patient was delivered by a mid forceps application on February 14. A right lateral episiotomy was done and repaired with No. 2 chromic catgut. The child, a boy, weighing 8 pounds, 11 ounces, was in good condition. The placenta was expressed after fifteen minutes, the uterus contracted well, and there was no undue bleeding.

The patient's temperature remained below 99.0°F until the evening of the fifth day. There was at the time a definite epidemic of streptococcal infection in the hospital, and what were believed

to be rigorous precautions were being taken to prevent its spread. On the evening of the fifth day the patient's temperature rose to 101.0°F., but the pulse was not affected. The fundus was well contracted, the lochia was not foul and the episiotomy wound appeared clean. Ice was applied to the fundus, an ampule of pituitary extract was given hypodermically, and half a teaspoonful of fluid extract of ergot was ordered to be given by mouth every four hours. The temperature continued to rise, reaching 104.0°F on the ninth day.

The white-cell count on the sixth day was 16,800. The blood sedimentation rate by Friedländer's method was ten minutes, and the hemoglobin was 65 per cent (Sahli). A blood culture taken on the ninth day showed no growth, and cultures taken on the eleventh, fifteenth and seventeenth days post partum were also negative.

The temperature remained at 104.0°F for two days and then dropped to 101. On the thirteenth day it rose to 103.0°F and continued to show a picket-type course, its highest point being 105.0 and its lowest 98.0, for seven days, after which time it dropped to normal.

On the eleventh day the sutures were removed from the episiotomy wound, a small amount of pus escaped, but the temperature was not affected. The lochia became somewhat foul on about the seventh day post partum.

Treatment was conservative. Food and fluids were forced and ice was applied intermittently to the fundus. Several courses of ergot by mouth were given. On the seventeenth day a transfusion of 250 cc. of citrated blood was given from a compatible donor. It was intended to follow this up with a series of small transfusions at intervals of a few days, but on the twentieth day the temperature dropped to normal and remained there during the rest of the patient's hospital stay.

The patient was discharged the twenty-third postpartum day. Discharge examination showed the uterus fairly well involuted, the vaults clear and the episiotomy wound clean although still granulating.

Comment. This is a case of institutional sepsis. Such cases may develop any time during the puerperium, this case showing no febrile reaction until the fifth day. Conservative treatment was followed. It is doubtful if the single transfusion had any effect on the course of the infection, although repeated small transfusions furnish one of the best ways of raising the patient's resistance. In cases of sepsis developing after three days it is presumable that the infection did not gain entrance at the time of delivery. It is possible that this infection was secondary to a throat in-

A series of selected case histories by members of the section will be published weekly. Comments and questions by subscribers are solicited and will be discussed by members of the section.

fection in the patient or was due to contamination following imperfect nursing care. In cases of epidemic infection all persons having anything whatever to do with the parturient patient should have throat cultures taken at least once a week and should be meticulous in the use of masks, furthermore, the care of utensils, bedpans and so forth must be scrupulous. As has been pointed out in this column before, the only way to combat institutional infection is perfect isolation, and if this cannot be obtained, closure of the institution is imperative.

DEATH

SHEA—MICHAEL I. SHEA, M.D., of Chicopee, died February 11. He was in his sixty-fifth year.

Born in Chicopee, he attended the local schools and Holy Cross College. He received his degree from Georgetown University School of Medicine in 1904 and later studied at Vienna. At the time of his death Dr. Shea was city physician and a member of the board of trustees of the Monson State Hospital. He was also chairman of the board of health and on the staff at Mercy Hospital.

Dr. Shea was a former member of the Massachusetts Medical Society.

His widow, two sons, two daughters, a brother and four sisters survive him.

MISCELLANY

GIFT FOR TUFTS

A gift of \$42,200 to the Tufts College Medical School from Dr. and Mrs. George G. Averill, of Waterville, Maine, was recently announced by President Leonard Carmichael. The fund, to be turned over to the school during the years of 1940 and 1941, will be devoted to the establishment of the Dr. and Mrs. George G. Averill Department of Anatomy in Memory of Professor Charles P. Thayer, President Carmichael said. Known as an industrialist, Dr. Averill was one of the first physicians graduated from Tufts nearly half a century ago.

The new medical school building, of which the gift will provide the entire top floor, will be situated in downtown Boston at the New England Medical Center, a location convenient to the Boston City Hospital and the other clinical teaching centers of the school, it was announced. It will be erected as soon as the entire \$750,000 needed has been obtained. Dr. Charles P. Thayer, in whose memory the gift was made, was one of the original seven founders of the school in 1893 and first head of the anatomy department.

In a statement accompanying his gift, Dr. Averill said: "The Tufts College Medical School has attained a singular position of responsibility to New England, since my graduation nearly a half-century ago these six states have come to depend more and more for their medical care and community health services on Tufts. Now the school trains more physicians for New England than any other medical school in the country. In the same period, anatomy has attained recognition as a mother science, embracing all fields of medicine, it is important that students who will be the physicians of tomorrow have the best opportunity to study a subject which has become one of the major biological sciences concerned with life processes. As

a New Englander I can think of no better investment than that which will support training at the school which is the chief source of our doctors."

RÉSUMÉ OF COMMUNICABLE DISEASES IN MASSACHUSETTS FOR DECEMBER, 1939

| DISEASES | DECEMBER 1939 | DECEMBER 1938 | FIVE YEAR AVERAGE* |
|--------------------------|------------------|------------------|-----------------------|
| Anterior poliomyelitis | 6 | 0 | 5 |
| Chickenpox | 1510 | 1096 | 1495 |
| Diphtheria | 20 | 23 | 36 |
| Dog bite | 577 | 561 | 515 |
| Dysentery bacillary | 26 | 14 | 7 |
| German measles | 26 | 55 | 121 |
| Gonorrhea | 335 | 400 | 517 |
| Lobar pneumonia | 396 | 415 | 447 |
| Measles | 1082 | 902 | 878 |
| Meningococcus meningitis | 1 | 5 | 8 |
| Mumps | 337 | 470 | 532 |
| Paratyphoid B fever | 2 | 6 | 2 |
| Scarlet fever | 412 | 506 | 468 |
| Syphilis | 433 | 480 | 443 |
| Tuberculosis pulmonary | 284 | 177 | 253 |
| Tuberculosis other forms | 28 | 23 | 28 |
| Typhoid fever | 5 | 3 | 8 |
| Undulant fever | 2 | 5 | 4 |
| Whooping cough | 511 | 784 | 839 |

*Based on figures for preceding five years.

RARE DISEASES

Anterior poliomyelitis was reported from Haverhill, 1, Lynn, 1, Revere, 1, Saugus, 1, Somerset, 1, Worcester, 1, total, 6.

Diphtheria was reported from Andover, 1, Boston, 3, Chelsea, 1, Dedham, 1, Foxboro, 2, Lawrence, 4, Methuen, 2, North Andover, 1, Revere, 2, Taunton, 3, total, 20.

Dysentery, bacillary, was reported from Amherst, 1, Boston, 1, Brookline, 1, Cambridge, 3, Everett, 1, Lee, 3, Lowell, 1, Lynn, 3, Malden, 6, Medford, 3, Wrentham, 3, total, 26.

Infectious encephalitis was reported from Boston, 1, total, 1.

Malaria was reported from Boston, 1, Taunton, 3, total, 4.

Meningococcus meningitis was reported from Pittsfield, 1, total, 1.

Paratyphoid B fever was reported from Brockton, 1, Peabody, 1, total, 2.

Pellagra was reported from Gardner, 1, Haverhill, 1, total, 2.

Septic sore throat was reported from Boston, 9, Braintree, 1, Cambridge, 1, Merrimac, 2, Milton, 1, New Ashford, 6, Williamstown, 2, total, 22.

Tetanus was reported from Quincy, 1, total, 1.

Trachoma was reported from Agawam, 1, Boston, 2, Brookline, 1, total, 4.

Trichinosis was reported from Boston, 1, total, 1.

Typhoid fever was reported from Agawam, 1, Boston, 1, Erving, 1, Newbury, 1, Weymouth, 1, total, 5.

Undulant fever was reported from Gardner, 1, Wilmington, 1, total, 2.

For the first time in several months the reported incidence of diphtheria fell below that for the previous year. Lobar pneumonia was reported well within the five year average.

Bacillary dysentery, primarily of the Sonne type, continues to be prevalent, although at a lower level than for the past several months.

Scarlet fever had its lowest reported December incidence since 1918.

Dog bite had its highest reported December incidence.

Measles continued to show an increased incidence, reaching a figure above the five year average.

There was nothing unusual about the reported incidences of anterior poliomyelitis, chickenpox, meningococcus meningitis, mumps, typhoid fever, paratyphoid fever, undulant fever, tuberculosis (pulmonary) and tuberculosis (other forms).

Whooping cough and German measles were reported well within the five year averages.

NOTES

The following appointments to the staff of the Harvard Medical School have been recently announced: Hans P. Mueller, M.D., University of Königsberg, 31 of Königsberg, Germany, as assistant in roentgenology; Ping Yang Liu, M.D., Hunan-Yale Medical College, 35 of Siangtan, Hunan, China, as research fellow in bacteriology and immunology; Carey M. Peters, M.D., Harvard, 36 of Spring Valley, New York, as assistant in medicine; Elias Strauss, M.D., Columbia, 37 of Roosevelt, New York, as research fellow in medicine; Herbert Lund, M.D., University of Pennsylvania, 31 of Uniontown, Pennsylvania, as research fellow in legal medicine.

John G. Scannell, a fourth-year student at the Harvard Medical School and the son of Dr. David D. Scannell, has been awarded the Henry Asbury Christian Prize, one of the outstanding honors of the Harvard Medical School. The prize is awarded to "the student in the fourth year class who has displayed diligence and notable scholarship and offers promise for the future." The award was established in 1937 in honor of Dr. Henry A. Christian, Harvey Professor of the Theory and Practice of Physics, Emeritus, a member of the Harvard Medical School staff since 1902.

CORRESPONDENCE

SYPHILIS PROJECT

To the Editor: Project No. 17568 (Op. No. 665-14-3-93) was established by the Works Projects Administration in 1937 for the study of the problem of syphilis in Metropolitan Boston. This work has been carried on successfully at the Boston City Hospital with the co-operation of the hospital authorities and members of the staff.

Many problems relating to syphilis have been undertaken, some of which have been satisfactorily dealt with while others are at present demanding the earnest attention of clinicians assisted by skilled technical workers. An analysis of the cost of syphilis in a large general hospital was published in the November 24, 1938 issue of the *Journal*.

A tremendous amount of material relative to syphilis and its management and end results has been collected and after proper classification and evaluation, final decisions will be published.

On the basis of the findings in thousands of case records at the Boston City Hospital, research work has been done in tabes dorsalis, cerebral thrombosis and syphilitic involvement of the spinal cord. Extensive studies have been made on syphilis in pregnancy, syphilis and alcoholism, and cardiovascular syphilis. Syphilitic lesions of the eye, as described and diagnosed in case records at the Boston City Hospital have been thoroughly studied and classified as to type, etiology, serology, therapy and outcome. Thousands of records of syphilitic cases have been abstracted. These abstracts have been transcribed to small cards that will be filed for future use by members of the hospital staff.

Bibliographic records relative to important contributions by the medical profession to the subject of syphilology have been prepared and filed in a convenient and easily accessible manner for ready reference.

Due to the inadequacy of the desired number of cases at the Boston City Hospital and also because of the paucity of information pertinent to our specific interests in the records, it has been thought wise to extend the scope of the study of congenital syphilis.

A previously attempted study of the lesions in the long bones of syphilitic infants in the first six months of life has stimulated a widespread interest in the subject of congenital syphilis, and as a result it has been proposed by the heads of various hospitals in Metropolitan Boston to conduct a survey of congenital syphilis covering a period of twenty years. It is obvious that the results of a survey of such magnitude would be more truly reliable and decidedly more representative than would the results of the findings from a single hospital in any particular community.

The aims of the project in regard to the above proposal may be briefly summarized, as follows:

1. To investigate the frequency and time of appearance of changes in the long bones of congenitally syphilitic children.
2. To determine the value of modern antisyphilitic treatment in congenital syphilis.
3. To carry out a follow-up system wherever possible, on those with congenital syphilis for the purpose of establishing the relative influence of modern antisyphilitic treatment on these patients with reference to their ultimate fate—physically, socially and economically.
4. To establish in each of the institutions mentioned a permanent file of the abstracted case records on congenital syphilis for the purpose of facilitating further research in the problem by the hospital staff.
5. To investigate the importance of syphilis as a factor in the causation of stillbirths, and to establish more definitely the frequency of osseous and visceral lesions in these patients.

It must be emphasized, however, that one of the principal aims of the project is to assist in the accumulation and ultimate distribution of facts about the disease to the public, as its part in the nationwide campaign to eradicate syphilis.

REPORT OF MEETING

SUFFOLK DISTRICT MEDICAL SOCIETY

A regular meeting of the Suffolk District Medical Society was held at the Boston Medical Library on November 29, with Dr Reginald Fitz presiding. Drs William Leifer, Louis Chargin and Harold T Hyman, of New York City, spoke on "The Theory and Practice of Massive Dose Chemotherapy by the Intravenous Drip Method in the Treatment of Syphilis." In introduction, Dr Hyman discussed the history of intravenous therapy in general, with particular reference to experiments which showed that many untoward reactions were the result of "speed shock" which stimulated nutritoid crises and anaphylactoid reactions. Due credit was given Dr Rudolph Matas, of New Orleans, who first used the intravenous route of therapy in 1888.

Dr Hyman went on to tell of the conditions of their clinical experiments with the intravenous method of treating syphilis by massive chemotherapy. All cases were studied by a special committee, and no patients were seen by the original group after the termination of the primary phase of the treatment. A six bed ward was provided at Mt. Sinai Hospital where the early cases were confined for one week. Follow up visits were made to specified clinics, for which one dollar was paid for

each visit as an inducement. Triplicate blood smears were collected for examination by recognized independent serologists. Upon return to the clinic, there was complete physical examination, but no treatment was to any case.

Dr Leifer then discussed the technical details of intravenous chemotherapy which was employed. Without any specific preparatory treatment, the patient entered the hospital, where they were immediately bedded. A 20-gauge needle was used, and the injection always made into a vein of the mid forearm, so minimal amount of immobilization was necessary. An initial infusion of 20 or 30 cc. of 5 per cent solution, 0.1 gm of arsphenamine in about 125 cc. same solution was allowed to run into the vein in one hour. At this rate for ten hours on four successive days, an average dose of about 4 gm. was administered. The patients were allowed out of bed each evening, less there was some individual contraindication. Recipients were given the routine hospital diet and carbohydrate fluids were forced. Pretreatment consisted of a complete blood count, a platelet or determination of the nonprotein-nitrogen level, the bilirubin content and a van den Bergh test. Measurements of the arsenic excretion showed that about 20 per cent recovered in the urine and somewhat over 30 per cent in the stools. Studies on bilirubin excretion on successive patients showed that 3 developed liver dysfunction. No patients showed any toxic or nutritoid reaction or local infiltration. However, 44 per cent developed mild phlebitis, and 24 per cent moderate nausea and vomiting, usually with the "primary fever." A few had headache and diarrhea.

Two types of fever developed. The primary occurred about five to seven hours after the first injection and was accompanied by the above mentioned symptoms. The phenomenon, which was similar to a heimer reaction, was noted in 57 per cent of the patients, but the temperature always returned to normal the same evening or by the next morning at the latest. Continuation of treatment resulted in no exacerbation. The secondary fever, which usually appeared about the fifth day, had an incidence of 63 per cent, was accompanied by toxic cutaneous eruptions in some instances and lasted from two to six days.

The dermatological reactions were usually noted between the sixth to the eighth day and were shown to be benefited by 200 mg of cevitamic acid daily. Toxicoderma, with an incidence of 52 per cent, was accompanied by fever, headache and arthralgia. If previous antisyphilitic treatment had been given, its effect was earlier.

Two patients showed clinical as well as laboratory evidence of jaundice, while a larger number showed evidence of subclinical jaundice in the form of an elevated icteric index and bile in the urine. This, however, compared favorably with the incidence of these conditions in the ordinary arsenical treatment of syphilis where 1 in 75 and 1 in 4 have clinical and subclinical jaundice, respectively.

A marked decrease of platelets occurred twice, but one patient had previously had thrombocytopenic purpura and was relieved by splenectomy, while the other had acted similarly to other methods of arsenical therapy. Daily urinalyses occasionally demonstrated a transient slight albuminuria which soon cleared. There were no significant casts, and the nonprotein nitrogen level remained normal.

Probably the most significant toxic manifestation

polyneuritis which occurred in 32 per cent of the group of patients and in 38 per cent of the second, the administration to the latter of presumably adequate amounts of thiamin chloride. The onset of symptoms was two to three weeks following discharge, and mild symptoms and minimal signs persisted for three months. There was never any motor involvement, only 4 of 86 patients were incapacitated during this period. All showed complete spontaneous recovery except one was only one fatality and the presence of a post-mortem test was cited as probable evidence that a hemiplegic encephalitis was the cause of death. Dr. Leifer stated that there is the same mortality rate (1 per cent) in the usual forms of treatment and that the unfortunate case was probably due to an inherent specific sensitivity to drug.

Chargin compared the results of their treatment of those of other types of antisyphilitic therapy. Satisfactory results were obtained in 89 per cent of 78 observed cases, as compared with the 80 per cent of favorable results in a typical series of continuously and alternately treated patients. There were no positive cerebrospinal fluid findings in any case. The principal advantage of the method were its short duration and the dosage of arsenicals necessary. It was even suggested that smaller total amounts of the drug might be used.

Hyman, in conclusion, enumerated the following stages of the continuous intravenous method of treatment of syphilis: the patient is made noninfectious within eight hours; 100 per cent of those starting the course attain final cure and the total arsenical dosage is

He said that they believed that, with the exception of the polyneuritis, all the so-called toxic manifestations were merely evidence of sensitivity to the drug.

Opening the discussion, Dr. Nels A. Nelson lauded the method as a possible boon to the public-health man, but of syphilis but deplored the unfortunate publication of it as a sure four-day cure for the disease. He felt would bring unbearable pressure on the physician to use the still experimental therapeutic cure. He also desired to know the cost of such a cure.

Hyman assured him that publicity was the last thing desired. The cost of approximately \$100 per patient was not considered a true criterion of the event since that included all experimental work.

Only criticism offered by Dr. William Boardman at a follow-up of two or three years was not adequate in cases entirely asymptomatic and free of disease. The speakers granted that this was merely a preliminary report of a long-term experiment.

Austin Cheever was of the opinion that, as yet, the reactions were too high to warrant the use of this method of therapy in a disease where 28 per cent of patients are cured without treatment and an equal number remain asymptomatic despite positive serological tests. His answer by Dr. Chargin was that it is impossible to know who are to be the lucky ones.

In answer to a question from Dr. Marshall Crawford, Hyman replied that no correlation had been attempted in the work of Eagles, who showed that a relative concentration of arsenicals inactivated the *treponema pallidum* in vitro. It was believed that too many additional factors play a role in vivo to make these applicable in practical chemotherapy.

NOTICES

FAULKNER HOSPITAL

The monthly clinicopathological conference of the Faulkner Hospital will be held on Thursday, March 7 at 5:00 p.m. There will be a discussion of cases by Drs. James A. Halsted and Arthur R. Kumpston.

Physicians and medical students are cordially invited to attend.

UNITED STATES MARINE HOSPITAL

The staff meeting of the United States Marine Hospital Chelsea, will be held at "The Hut," on Friday after noon, March 1 at 4:00. Mr. John C. G. Loring will talk, his subject being "Neurotic Alcoholism."

MASSACHUSETTS GENERAL HOSPITAL

A meeting of the Hospital Research Council will be held in the Ether Dome of the Massachusetts General Hospital, on Tuesday February 27, at 5:00 p.m.

PROGRAM

The Passage of Thiocyanate and Glucose from the Blood Stream into the Joint Spaces. Dr. J. W. Zeller

Analysis of the Acoustics of the Stethoscope. Dr. H. B. Sprague and Mr. Maurice Rappaport.

Comparative Studies of the Effects of 200-Kilovolt and 1000-Kilovolt Roentgen Rays. The biologic effects on bone marrow growing epiphyses and skin. Dr. E. A. Gall.

JEWISH MEMORIAL HOSPITAL

A meeting of the staff of the Jewish Memorial Hospital will be held in the hospital auditorium, 45 Townsend Street, Roxbury on Thursday evening, February 29 at 8:30.

Dr. Joseph H. Pratt will speak on the subject "Pancreatic Disease." There will be an open discussion followed by a collation.

The medical profession is cordially invited to attend.

HARVARD MEDICAL SOCIETY

The next meeting of the Harvard Medical Society will be held on Tuesday February 27 in the amphitheater of the Peter Bent Brigham Hospital (Shattuck Street entrance) at 8:15 p.m.

PROGRAM

Presentation of cases.

The Life History of Bone Grafts. Experimental and clinical observations. Dr. Ralph K. Ghormley, Mayo Clinic, Rochester, Minnesota.

Medical students and physicians are cordially invited to attend.

BOSTON DISPENSARY

A luncheon meeting of the clinical staff of the Boston Dispensary will be held on Tuesday February 27 in the auditorium of the Joseph H. Pratt Diagnostic Hospital at 12 o'clock noon. The subject of the meeting will be "The New England Medical Center. Its origin, present activities and future plans" by Mr. Arthur G. Roach.

This meeting will inaugurate a series of talks on the past, present and future of the New England Medical Cen-

ter and its component parts Talks in the following months will be given by Dr Charles C Cabot and Mr Frank E. Wing on the Boston Dispensary, Dr Leonard J Carmichael on the Tufts College Medical School, Dr Elmer W Barron on the Boston Floating Hospital and Dr Joseph H Pratt on the Pratt Diagnostic Hospital Luncheon will be served to non members at 35 cents All interested persons are cordially invited to attend

PETER BENT BRIGHAM HOSPITAL

A joint medical and surgical clinic at the Peter Bent Brigham Hospital will be held on Wednesday, February 28, from 2 to 4 p.m Drs Lyman Richards and Soma Weiss will speak on "Sore Throat"

Physicians and students are cordially invited to attend

PETER BENT BRIGHAM HOSPITAL

A research conference of the medical staff of the Peter Bent Brigham Hospital will be held in the amphitheater of the hospital on Tuesday, March 5, at 5 00 p.m

PROGRAM

- Blood and Urine Iodine in Diabetes Insipidus Drs H H Blotner and H J Perkin
Further Observations on Dynamics of Circulation in Patent Ductus Arteriosus Dr E C Eppinger

All interested persons are cordially invited to attend

NEW ENGLAND SOCIETY OF PHYSICAL MEDICINE

There will be a meeting of the New England Society of Physical Medicine at 8 00 on Wednesday evening, February 28, at the Hotel Kenmore, Boston An informal dinner will be held in the Empire Room at 6 30

PROGRAM

- Symposium on the Treatment of Arthritis
1 Orthopedics Dr L T Swaim
2 Diet and Hygiene for the Arthritic Dr J P Bill
3 The Use and Abuse of Physical Agents Dr H A Osgood.

All members of the medical profession are cordially invited to attend.

EDWARD K DUNHAM LECTURES

The Faculty of Medicine of Harvard University has announced that the following lectures will be given by Dr S Walter Ranson, professor of neurology and director of the Institute of Neurology, Northwestern University Medical School, Chicago, under the Edward K. Dunham Lectureship for the Promotion of the Medical Sciences

Monday, March 4 The Hypothalamus and the Sympathetic Nervous System.

Wednesday, March 6 Hypothalamicohypophysial Relationships

Friday, March 8 The Hypothalamus and Behavior

These lectures are scheduled for 5 00 p.m. at the Harvard Medical School, Amphitheater, Building C

NEW ENGLAND PATHOLOGICAL SOCIETY

The meeting scheduled for February 15 was not held because of the storm and has been rescheduled for Thursday, February 29, at 8 00 p.m at the Tufts College Medical School, 416 Huntington Avenue, Boston

PROGRAM

- Pathological Observations in Simmonds' Disease. I R C Wadsworth
Immediate Wheal and Erythema Type Reactions Simple Chemical Substances Dr John Jacobs
Pathological Findings in Leukoerythroblastic Anemia Dr S B Thorson
Primary Tumor of the Heart. Dr Harold Wood.

The pathological demonstrations will be available 7 00 p.m There will be a short business meeting followed by a collation

Physicians and students are cordially invited to attend

NORFOLK DISTRICT MEDICAL SOCIETY

The regular meeting of the Norfolk District Medical Society will be held in the Hotel Somerset, Boston, Tuesday evening, February 27, at 8 30 Tel KEN 2700.

PROGRAM

Business

The Uses and Abuses of Sulfanilamide and Related Compounds Dr Chester S Keefer Discusses will be opened by Dr John F Casey

Collation

AMERICAN PHYSICIANS' ART ASSOCIATION

The American Physicians' Art Association, composed of over eight hundred physicians in the United States, Canada and Hawaii who follow some form of fine or applied art as an avocation, will hold its next annual art show at the Belmont-Plaza, New York City, June 10-14, during the annual session of the American Medical Association All physicians, in active practice or retired, who have an art hobby, including photography, are cordially invited to participate in the New York exhibit.

A physician may join this association by mailing a check for one dollar to the treasurer, Dr R W Burlingame, San Francisco County Hospital, San Francisco, California, briefly stating what art medium the applicant follows For detailed information kindly write to the executive secretary, Dr F H Redewill, 526 Flood Building, San Francisco, California.

SOCIETY MEETINGS AND CONFERENCES

CALENDAR OF BOSTON DISTRICT FOR THE WEEK BEGINS SUNDAY, FEBRUARY 25

SUNDAY FEBRUARY 25

- 4 p.m Sterility (lecture for women only) Dr Donald Free public lecture. Harvard Medical School, amphitheater Building D
4 p.m Surgery of the Blood Vessels and Extremities. Dr E. E. O'Neil Illustrated, public health lecture. Faulkner Hall auditorium

MONDAY FEBRUARY 26

- *8 15 p.m New England Heart Association Children's Hosp Boston

TUESDAY FEBRUARY 27

- *9-10 a.m Suppurative Disease of the Lungs Dr L F Dancy Joseph H Pratt Diagnostic Hospital
*12 m The New England Medical Center: its origin present and future plans Mr Arthur G Roitch Boston Dispensary
5 p.m Hospital Research Council, Massachusetts General Hospital
*8 15 p.m The Life History of Bone Grafts Experimental and observations Dr Ralph A Ghormley Harvard Medical School Peter Bent Brigham Hospital (Shattuck Street entrance)
8 30 p.m The Uses and Abuses of Sulfanilamide and Related Compounds Dr Chester S Keefer Norfolk District Medical Society Hotel Somerset Boston

WEDNESDAY FEBRUARY 25

- 9-10 a.m. Hospital case presentation. Dr. S. J. Thannhauser. Joseph H. Pratt Diagnostic Hospital.
2-4 p.m. Fore throat. Drs. Lyman Richards and Norma Wells. Peter Best Brigham Hospital.
8 p.m. New England Society of Physical Medicine. Hotel Kenmore, Boston.

THURSDAY FEBRUARY 26

- 9-10 a.m. Derangements of the knee. Arthur A. Thibodeau. Joseph H. Pratt Diagnostic Hospital.
5 p.m. Renal Physiology. Dr. Donald D. Van Slyke. Harvard chapter of Nu Sigma Nu. Harvard Medical School, Bulfinch St. E.
8 p.m. New England Pathological Society. Tufts College Medical School.
8:30 p.m. Staff meeting. Jewish Memorial Hospital. 45 Townsend Street, Roxbury.

BOOK REVIEWS

The Evolution and Organization of the University Clinic
Simon Flexner. 41 pp. New York: Oxford University Press, 1939. \$1.25.

Two lectures given at the Nuffield Institute in Oxford in January 1938, by the Eastman Visiting Professor have been published in pamphlet form. They are distinctly worthy of preservation for much of the history of the development of the university clinic is contained in Dr. Flexner's brilliant review of this subject. As historical documents, these lectures are invaluable. Beginning with the first teaching laboratory of modern times, founded by Liebig in 1825 one is carried through the development of the university laboratory by Purkinje in 1842 and von Ziemssen in 1884 to the period of Virchow, Müller and Schönlein. Schönlein was followed by Frerichs and later by Traube and many others. American developments came much later. The first was that of Bowditch a pupil of Ludwig at the Harvard Medical School in 1871 and five years later Johns Hopkins University established a laboratory in biology including physiology for Newell Martin, a pupil of Huxley and Foster. In 1889 the year the Johns Hopkins Hospital was opened, most diagnostic laboratories were attached to the wards, but in 1893 with the founding of the medical school laboratories were established in relation with the pre-clinical sciences. The first actual hospital built wholly for research in clinical medicine, was that established by the Rockefeller Institute in 1910, in which Welch took a leading part. The latest addition to the long list of laboratories now established is that of the Nuffield Institute established by Lord Nuffield, long a friend of medicine. It seems not unlikely that the idea was implanted in Lord Nuffield's mind by Osler soon after he went to Oxford in 1905. The new laboratories with their full-time professorships should become an important center for medical research. No one could give them a happier start in medicine than Simon Flexner. These two lectures should be widely read by the medical profession in general.

Hospital Public Relations Alden B. Mills. 361 pp. Chicago: Physicians Record Co. 1939. \$3.75.

This book reflects the changing attitude of the public toward hospitals and of the hospitals toward their communities. Time was when hospitals were regarded with dread now they offer hope and inspire confidence. In the first chapters Mr. Mills sets forth some of the rea-

sons for this change of opinion, and the remainder of the book is devoted to showing why hospitals should explain themselves to the public and, since there is a right way and a wrong way, how it should be done. Inasmuch as hospital ethics closely follow medical ethics, it is necessary to remember that any public-relation program must respect the privacy of the patient and that the institution must avoid what might be termed advertising. Of course, one of the prime motives of public relations is to obtain support for the hospital, not only financial but also moral. In either case the program must be carefully prepared and thoroughly carried out. Careless and hasty planning and half-hearted or slipshod presentation spell failure.

The second part, which deals with methods of application of the theories of public relation set forth in the preceding chapters, contains a most complete and detailed list of the various ways of presenting the hospital's case to the public and also just how it should be done. Annual reports, pamphlets, letters, newspaper articles, motion pictures and radio programs are mentioned and explained. The chapter on fund raising should be read by all who contemplate such a campaign.

This book can be read with profit by all hospital administrators. They will find many valuable and stimulating ideas, which are intelligently set forth, and will probably adopt and carry out many of them. Trustees will find it crammed with ideas, new to many of them, which are informative and are sure to prove helpful in their relations to the hospital personnel and particularly valuable in guiding the relation of their hospital to the public.

It is a well-written book by a man, trained in civic and social affairs, who served as executive secretary to the Committee on the Costs of Medical Care and who at present is managing editor of *The Modern Hospital*.

Surgical Applied Anatomy Frederick Treves Tenth edition. 748 pp Philadelphia Lea & Febiger, 1939 \$4.00

This work, crammed full of practical information tersely expressed, has reached its tenth edition. This revision is by Lambert Rogers, professor of surgery at the University of Wales, who states in the preface "To be invited to prepare a tenth edition of this long-established textbook, and thereby follow such distinguished revisors as Sir Arthur Keith and the late Professor C. C. Choyce, was an honour not lightly to be declined, albeit a task from which one might reasonably have shrunk." Rogers has attempted to re-establish the original design of the work and to eliminate modifications which have crept into previous revisions. The sections on the eye, ear, nose and throat have been modernized by his colleagues at the Cardiff Royal Infirmary, Messrs Parry and Owen. He has also incorporated nine illustrations from *Everyday Surgery*, written by himself and d'Abreu.

Although Treves's work was originally intended for the use of surgical students, induding "the dull items of anatomy with meaning and interest by the aid of illustrations drawn from common medical and surgical experience," it is a valuable reference book for practitioners. The treatment of certain human ailments requires a knowledge of anatomy. Without this knowledge the treatment of these conditions cannot be intelligent, it can be nothing more than the blind following of generally accepted rules. The medical man who practices by rules misses the stimulation which springs from the thoughtful contemplation of fundamental knowledge. His efforts to care for patients cannot long be characterized by that vigor

and enthusiasm so vital in promoting comforting confidence.

A splendid double column index of thirty five pages, nearly two hundred illustrations, excellent typography and flexible covers make this small volume a handy reference book. It is highly recommended to all practitioners and students.

Illustrations of Regional Anatomy E. B. Jamieson. Second edition. Seven sections, 305 pp. Sections I to inclusive, Edinburgh E. & S. Livingstone, 1937. Sections VI and VII, Baltimore Williams & Wilkins Co. 1939. Complete set, \$15.00.

Jamieson is senior demonstrator and lecturer in anatomy at the University of Edinburgh. In 1934 he published five small atlases of anatomical diagrams and drawings illustrating the central nervous system, head and neck, abdomen, pelvis and thorax. They were well received and calls for illustrations of the limbs were so persistent, that the author has not only published two volumes to cover the extremities but has revised the entire work. This second edition consists of over three hundred loose-leaf plates, many in several colors, assembled in seven sections, with flexible cardboard covers (6½ by 8¼ in.).

The plates are beautifully done and a joy to study. The diagrams and views for the most part differ from those found in general works on human anatomy, they constitute a valuable supplement to any such volumes the student may own. Their small size and compactness render them conveniently useful in the lecture room and laboratory. Their reasonable cost is another attractive feature. Individual sections may be purchased and vary in price from \$1.50 to \$3.50.

The Rectum and Colon E. Parker Hayden. 434 pp Philadelphia Lea & Febiger, 1939 \$5.50

This book is a comprehensive treatise of the minor and major diseases involving the colon, rectum and anus. Primarily surgical in nature the accepted non-surgical procedures are discussed and indications given for the use of the various methods described.

The book is very well organized, and the illustrations, whether photographs or drawings, are clear and helpful. It is well written, detailed but not cyclopedic. Controversial subjects are given ample discussion, and the reader is always given a definite opinion as to the procedure indicated, based on the experience of the writer and his associates at the Massachusetts General Hospital.

The reviewer has no hesitation in recommending this book. It is sufficiently detailed to be of value and sufficiently practical to be helpful to the student, proctologist and general surgeon.

Baptism of the Infant and the Fetus. An outline for the use of doctors and nurses J. R. Bowen. Fourth edition. 12 pp. Dubuque The M. J. Knappell Co., 1938 25c.

This pamphlet is most valuable for doctors and nurses especially in hospital practice where all denominations are treated. Since religious practices and beliefs are very sacred to the communicants of various religions and since the doctor is in many instances considered a clergyman, he should familiarize himself with these procedures for the emergency. It is well prepared and can be absorbed at one reading.

NUMBER 9

THE VALUE OF ROUTINE BLOOD-PROTEIN DETERMINATIONS*

Report of Results in 320 Consecutive Cases

H. H. SHUMAN, M.D.,† AND HAROLD JEGHERS, M.D.‡

BOSTON

RECENT medical literature is replete with papers stressing the clinical importance of blood-protein determinations. Unfortunately the complexity of quantitative protein determinations has hindered the widespread use of this procedure.

Until recently the most widely used methods for blood-protein determinations included the macro- and micro-Kjeldahl, the colorimetric and the refractometric methods. These are complex procedures, relatively expensive as to equipment and to upkeep, and time-consuming even in the hands of experienced technicians. Both the clinician and the laboratory worker have long been in search of simpler methods. Several have been introduced and, though helpful, lacked quantitative accuracy.

The recently introduced Kagan's^{1,2} method compared for the first time simplicity with the desired quantitative accuracy. This method is rapid, the apparatus is inexpensive and the technique can be readily mastered by any technician.

Kagan checked the accuracy of this method against the macro-Kjeldahl method and found the greatest deviation in 107 specimens to be 0.48 gm per 100 cc., with a mean deviation of 0.16 gm. For clinical purposes such small deviations are irrelevant.

On the medical services of the Boston City Hospital it is customary to order blood-protein determinations only when specifically indicated, because the total number performed by the laboratory must necessarily be limited. The acquisition of a Kagan proteinometer by one of us (H. H. S.) suggested the idea of doing routine blood-protein determinations on a large series of consecutive admissions to the Fifth Medical Service. The present

paper summarizes and discusses the results secured in 320 such cases.

METHOD AND PROCEDURE

The falling drop method for determination of specific gravity was first published by Barbour and Hamilton.³ Moore and Van Slyke⁴ later worked out the relation between plasma specific gravity and plasma protein content. Kagan, using this knowledge, devised a practical clinical test whereby the total protein of blood could be determined by noting the rate at which a drop of serum or plasma fell a measured distance through a mixture of synthetic methyl salicylate and heavy California mineral oil. The principle of this method is based on Stokes law and is described in Kagan's papers. A standardized apparatus for performing this test is now available commercially.⁵

The technique used in our study was as follows: the blood of 320 patients admitted to the Fifth Medical Service during April and May, 1939, was subjected to Kagan's test, the blood sample being collected at the same time as that for the routine Hinton test. Two cubic centimeters was placed in a small, dry test tube and centrifuged until the serum separated from the clot. The serum and proteinometer were allowed to remain at room temperature for ten minutes before using. Kagan's technique was followed. By means of a calibrated pipette 0.015 cc. (15 cu. mm.) of serum was introduced into the glass cylinder of the proteinometer and the time required for the drop of serum to fall 10 cm. through the oil was measured to one-tenth of a second by means of a stopwatch. The protein value of the serum was obtained from a calibrated chart, due correction being made for the temperature of the oil. Most of the determinations required less than one minute for their completion, and all were made by one of us (H. H. S.). A dietary history, obtained by clinical clerks working on the service, was available in the majority

†Formerly assistant physician, South Department, Boston City Hospital; physician, Burbank Hospital, Fitchburg, Massachusetts.

‡Assistant professor of medicine, Boston University School of Medicine; senior visiting physician, Boston City Hospital.

⁵The Kagan proteinometer was obtained from E. H. Sargent & Co., Chicago.

sons for this change of opinion, and the remainder of the book is devoted to showing why hospitals should explain themselves to the public and, since there is a right way and a wrong way, how it should be done. Inasmuch as hospital ethics closely follow medical ethics, it is necessary to remember that any public-relation program must respect the privacy of the patient and that the institution must avoid what might be termed advertising. Of course, one of the prime motives of public relations is to obtain support for the hospital, not only financial but also moral. In either case the program must be carefully prepared and thoroughly carried out. Careless and hasty planning and halfhearted or slipshod presentation spell failure.

The second part, which deals with methods of application of the theories of public relation set forth in the preceding chapters, contains a most complete and detailed list of the various ways of presenting the hospital's case to the public and also just how it should be done. Annual reports, pamphlets, letters, newspaper articles, motion pictures and radio programs are mentioned and explained. The chapter on fund raising should be read by all who contemplate such a campaign.

This book can be read with profit by all hospital administrators. They will find many valuable and stimulating ideas, which are intelligently set forth, and will probably adopt and carry out many of them. Trustees will find it crammed with ideas, new to many of them, which are informative and are sure to prove helpful in their relations to the hospital personnel and particularly valuable in guiding the relation of their hospital to the public.

It is a well written book by a man, trained in civic and social affairs, who served as executive secretary to the Committee on the Costs of Medical Care and who at present is managing editor of *The Modern Hospital*.

Surgical Applied Anatomy Frederick Treves Tenth edition 748 pp Philadelphia Lea & Febiger, 1939 \$4.00

This work, crammed full of practical information tersely expressed, has reached its tenth edition. This revision is by Lambert Rogers, professor of surgery at the University of Wales, who states in the preface "To be invited to prepare a tenth edition of this long-established textbook, and thereby follow such distinguished revisors as Sir Arthur Keith and the late Professor C. C. Choyce, was an honour not lightly to be declined, albeit a task from which one might reasonably have shrunk." Rogers has attempted to re-establish the original design of the work and to eliminate modifications which have crept into previous revisions. The sections on the eye, ear, nose and throat have been modernized by his colleagues at the Cardiff Royal Infirmary, Messrs Parry and Owen. He has also incorporated nine illustrations from *Everyday Surgery*, written by himself and d'Abreu.

Although Treves's work was originally intended for the use of surgical students, induding "the dull items of anatomy with meaning and interest by the aid of illustrations drawn from common medical and surgical experience," it is a valuable reference book for practitioners. The treatment of certain human ailments requires a knowledge of anatomy. Without this knowledge the treatment of these conditions cannot be intelligent; it can be nothing more than the blind following of generally accepted rules. The medical man who practices by rules misses the stimulation which springs from the thoughtful contemplation of fundamental knowledge. His efforts to care for patients cannot long be characterized by that vigor

and enthusiasm so vital in promoting comforting confidence.

A splendid double-column index of thirty-five pages, nearly two hundred illustrations, excellent typography, flexible covers make this small volume a handy reference book. It is highly recommended to all practitioners and students.

Illustrations of Regional Anatomy E. B. Jamieson. Second edition. Seven sections, 305 pp. Sections I to VI inclusive, Edinburgh: E & S Livingstone, 1937. Sections VI and VII, Baltimore: Williams & Wilkins, 1939. Complete set, \$15.00.

Jamieson is senior demonstrator and lecturer in anatomy at the University of Edinburgh. In 1934 he published five small atlases of anatomical diagrams: drawings illustrating the central nervous system, head and neck, abdomen, pelvis and thorax. They were well received and calls for illustrations of the limbs were so persistent, that the author has not only published four volumes to cover the extremities but has revised the first work. This second edition consists of over two hundred loose leaf plates, many in several colors, assembled in seven sections, with flexible cardboard covers (6½ by 8¼ in.).

The plates are beautifully done and a joy to study. The diagrams and views for the most part differ from those found in general works on human anatomy, and constitute a valuable supplement to any such volumes a student may own. Their small size and compactness render them conveniently useful in the lecture room or laboratory. Their reasonable cost is another attractive feature. Individual sections may be purchased and vary in price from \$1.50 to \$3.50.

The Rectum and Colon E. Parker Hayden. 434 pp. Philadelphia: Lea & Febiger, 1939. \$5.50.

This book is a comprehensive treatise of the minor and major diseases involving the colon, rectum and anus. It is primarily surgical in nature; the accepted non-surgical procedures are discussed and indications given for the use of the various methods described.

The book is very well organized, and the illustrations, whether photographs or drawings, are clear and helpful. It is well written, detailed but not cyclopedic. Controversial subjects are given ample discussion, and the reader is always given a definite opinion as to the procedure indicated, based on the experience of the writer and his associates at the Massachusetts General Hospital.

The reviewer has no hesitation in recommending this book. It is sufficiently detailed to be of value and sufficiently practical to be helpful to the student, proctologist and general surgeon.

Baptism of the Infant and the Fetus. An outline for the use of doctors and nurses J. R. Bowen. Fourth edition. 12 pp. Dubuque: The M. J. Knippel Co., 1935. 25c.

This pamphlet is most valuable for doctors and nurses especially in hospital practice where all denominations are treated. Since religious practices and beliefs are very sacred to the communicants of various religions, and since the doctor is in many instances considered a clergyman, he should familiarize himself with these procedures for the emergency. It is well prepared and can be absorbed at one reading.

uve thyroid crisis brings the subject within the province of the thyroid surgeon.¹² The condition may be the responsible factor or at least aggravate certain types of toxemia of pregnancy, thus making the subject of interest to the obstetrician.¹³ No doubt future studies will determine more fully the significance of hypoproteinemia.

The common causes of hypoproteinemia are given in Table 2. The complexities of this subject have been well reviewed by Melnick and Cowgill¹⁴ and Moschcowitz,¹⁵ and need no further comment here.

RESULTS

A summary of the general results is shown in Table 3. In the group of 320 patients, 238 (74.5

cc., with 5 of them (22 per cent) showing edema. In only 1 case (a patient with avitaminosis) was there general anasarca. The diagnoses of patients in this group are given in Table 4, together with

tion and utilization, loss of blood and heart disease were important additional factors producing hypoproteinemia in some of these cases. Two patients had clinically recognizable beriberi, 1 had the classical picture of scurvy, and 1 evidenced

Edema here refers to peripheral pitting edema present on admission.

generalized vitamin deficiency. Less clear-cut evidence of deficiency—that is, dry or rough skin, stomatitis, glossitis, soft gums—was present in most of the other patients in this group, but such findings are naturally difficult to evaluate.

The large number of low protein values in our series suggested to us the necessity of checking the method in a group of healthy normal persons partaking of an adequate diet. Therefore, blood from 25 individuals (physicians, medical students, orderlies and technicians) was obtained and analyzed by the Kagan technic for total blood protein. The results are tabulated in Table 6. All,

average deviation of 0.14 gm. Our results indicate clearly that the detailed chemical procedures are no more accurate for routine work than is the Kagan technic, and might well be dispensed with in any busy hospital laboratory.

In only 1 case was hyperproteinemia discovered, a value of 8.73 gm per 100 cc being obtained in a case of multiple myeloma. The formol-gel and Takata-Ara tests were strongly positive, which suggested, although the albumin-globulin ratio was not determined, that the globulin fraction was greatly increased. The main clue to the diagnosis in this case was the hyperproteinemia. Our results show that hyperproteinemia is considerably less common than hypoproteinemia, at least among the average run of medical cases seen in this district. On an active medical service one would be unlikely to find more than five or ten cases in the course of a year. The diagnostic significance of the condition is so great, however, that even the rare case is worthy of consideration.

It has been stressed that the protein level of 8 gm per 100 cc or over for the diagnosis of hyperproteinemia is only relative, for actually it is the presence of hyperglobinemia that is the more significant.⁷ The Takata-Ara test is said to be positive when the globulin fraction is over 3 gm per 100 cc¹⁶ and the formol-gel test usually positive when the globulin value reaches 4 gm.¹⁷ For routine clinical work these simple laboratory procedures suffice to detect globulin increase and should be done along with the Kagan technic wherever possible. Only rarely will it be necessary to determine the globulin fraction by chemical analysis. Therefore, one should view any total protein of 7 gm per 100 cc or over with the same suspicion attached to values over 8 gm per 100 cc, provided the albumin-globulin ratio proves to be reversed. It would perhaps be wisest to have every protein determination, regardless of its level, accompanied by some estimate of the globulin fraction.

COMMENT

It was a distinct surprise to find that almost 20 per cent of the patients in this series had a protein value below normal, 12.1 per cent of the determinations were less than 5.5 gm per 100 cc, and 5.3 per cent were less than 5.0 gm (the level commonly accepted as being clinically significant). Edema was distinctly commoner in the low protein group, so much so, that in this hospital, at least, one would be justified in considering hypoproteinemia as the main, or at least a contributory, mechanism each time an edematous patient is studied. The difficulty of controlling cardiac decompensation in the presence of hypoproteinemia is particularly important,¹⁸ and is probably

TABLE 6 Protein Values on Blood from 25 Normal Persons, Ages 24 to 35

| BLOOD PROTEIN gm per 100 cc | NO. OF CASES |
|--------------------------------|--------------|
| 5.70-6.00 | 2 |
| 6.01-6.30 | 12 |

| 6.61-6.90 | 1 |
| 6.91-7.20 | 2 |

with 2 exceptions (5.93 and 5.70 mg per 100 cc) fell within the normal range. No adequate explanation for these two low values could be ascertained, the diet in each case being adequate. One could conclude that the low values for the hospital patients were not due to a tendency for this method to give low readings, but represent true cases of hypoproteinemia.

This is further shown to be true by comparing the 20 total blood-protein values obtained by the hospital chemical laboratory, where the standard

macro- and micro-Kjeldahl methods are used, with those obtained by the Kagan technic. The figures are shown in Table 7. It can be seen that the greatest variation was 0.49 gm per 100 cc, with an

often overlooked. In other words, the presence of edema in any form indicates the necessity for determining the blood protein level.

The influence of dehydration on the blood protein level was not considered in our patients but is extremely important. It is common for very ill patients to be dehydrated on admission, thus increasing the total protein value of the blood. With restoration of the fluid to normal, subsequent determinations may show the blood protein to be diluted sufficiently to produce hypoproteinemia. Therefore, a true estimate of the blood protein level cannot be secured until the fluid balance of the body has been restored to normal. This should be especially considered in those clinics where it is customary to take blood specimens immediately after the patient is admitted to the ward.

It is now generally accepted that few nutritional deficiencies occur singly. The discovery of one indicates the presence of others, even though not marked enough for clinical recognition. In this sense, the determination of the total blood protein value is at present the easiest laboratory test available for detection of a dietary deficiency. The presence of hypoproteinemia indicates the need for a dietary history and a thorough search for the clinical minutiae suggestive of other deficiencies.

In our own series, abnormal protein values were found as commonly as significant deviations from normal in the routine urinalyses, blood nonprotein nitrogen and sugar determinations, blood counts, Hinton reactions and so forth.

In the past, technical difficulties discouraged follow-up studies on patients with abnormal protein values. This technic encourages such studies.

With regard to treatment, it is obvious that most persons with hypoproteinemia will respond favorably to dietary measures alone. However, the presence of liver disease and poor gastrointestinal absorption or utilization may preclude such a simple approach. Where necessary, intravenous therapy in the form of blood transfusion or, if available in the future for general human use, injections of lyophilic serum¹⁰ or aminoacids¹¹ would be indicated for temporarily increasing the blood protein

level. The latter methods have potentialities certain to stimulate further studies.

SUMMARY

The blood-protein level for each of 320 medical patients and 25 controls was determined by the Kagan falling-drop technic. The method proved not only accurate but so simple that routine determinations were easily possible. Our results indicate that abnormal blood-protein values are commonly found on a general medical service. The significance of such changes has been briefly reviewed and discussed in the light of our results.

SURGICAL PROBLEMS IN DIVERTICULITIS*

E. PARKER HAYDEN, M.D.†

BOSTON

BEFORE proceeding to a discussion of the surgical aspects of diverticulitis certain recognized facts relating to diverticulosis and to uncomplicated diverticulitis should be emphasized

In the first place, diverticula seldom occur in people under forty and are most often found in obese men over that age. During routine gastrointestinal x-ray examinations diverticula are found in 3 to 10 per cent of patients. At the Massachusetts General Hospital, for example, in 6426 consecutive barium-enema examinations, they were revealed in 3 per cent of the cases. Of this percentage only a small number of persons are likely to develop diverticulitis to a degree which will bring them to a doctor and permit a definite diagnosis to be made. The sigmoid is the commonest site of diverticulum formation, and diverticula are also most numerous in this area—both factors decreasing as the cecum is approached. The sigmoid is likewise by far the most frequent site of diverticulitis, even though the entire colon may be studded with diverticula. Diverticula without evidence of spasm by x-ray examination, and without clinical evidence of inflammation, need no treatment except encouragement of normal eating and bowel habits, in order to lessen the likelihood of diverticulitis. When inflammation does develop, the patient remains a medical problem unless complications of perforation or obstruction occur. In such an event, although operative procedures are not necessary in every case, the patient should be promptly observed by a surgeon, who can best assume the responsibility of deciding this point and carrying out the proper procedure. Finally, mild intermittent attacks of diverticulitis may go on for years without the occurrence of a perforation or of serious obstruction, while other cases are more fulminating and demand surgical procedures of varying number and degree.

ACUTE DIVERTICULITIS

A patient during an acute attack, with fever, pain and a palpable, tender mass, usually in the left lower quadrant, inevitably has an associated period of obstipation, due to temporary swelling

and obstruction in the sigmoid. Usually this situation does not demand surgery. Such an individual is best treated by rest in bed, morphine, the giving of fluids, freely by vein and in moderation by mouth, heat or cold applied locally for comfort, and abstention from the use of an enema until the process is definitely subsiding. Even then an enema should be given with extreme caution, using not over a pint of water, since perforation can be produced by fluid pressure. Mineral oil administered by mouth and by rectum in small amounts after four or five days is safe and of some benefit. No cathartics should be given. Under this type of treatment most cases will have subsided by the end of a week, the fever dropping, the pain lessening, the mass becoming less evident and bowel function re-establishing itself. On the other hand, persistence of or an increase in temperature, pain, tenderness and the size of the mass suggests the likelihood of a walled-off abscess from slow perforation, for which an operation will probably be necessary. It should also be remembered, however, that a small abscess resulting from perforation may establish spontaneous drainage into the bowel and recovery may ensue without operation. I have had at least 2 patients who were very sick for ten to fourteen days and in whom this unquestionably occurred, as determined later by barium enemas which revealed a perisigmoidal cavity in each.

It is a matter of considerable importance to decide rightly whether or not to explore a case of diverticulitis during an acute episode, and also to determine the best procedure after entering the abdomen.

I have reviewed the records of 140 cases of diverticulitis treated at the Massachusetts General Hospital by various surgeons from 1911 to 1936 inclusive, and also 35 cases from my own files. The figures in this paper, however, are based only on the former group. Of the 140 patients, 63 were operated on one or more times (Table 1), while 77 were treated without surgery. The number of operated cases in proportion to the total is, of course, much higher than would be true in a group of cases seen outside a hospital, since as a rule the sickest patients go to hospitals. Thus, in the 35 cases from my private practice, operative procedures were carried out in only 5 cases, or about 14 per cent of the total.

Exploration of Uncomplicated Cases

Of the 63 Massachusetts General Hospital cases submitted to operation, 12 were explored during an acute attack and a mass in the sigmoid with out evidence of perforation was found. Of the 12 patients, 8 were sewed up without drainage and all recovered except 1, who died of peritonitis, due apparently to a perforation into the peritoneal cavity, which developed the day after operation. In the remaining 4 cases a drain was placed in the

latter died later of carcinoma, which was probably present originally. The 7 deaths from peritonitis might have been avoided by a delay in operation until the abscess either drained spontaneously into the bowel or increased sufficiently in size to be accessible through the rectum or the vagina or beneath the abdominal wall. In this group of cases, a cecostomy was performed at the same time in 1 of the 7 fatal cases and in 1 of the 7 recovered cases, a fact which seems to indicate that such a procedure is an unnecessary adjunct to simple drainage under such circumstances.

Three other acute cases developed low pelvic abscesses which were opened through the vagina, all the patients left the hospital, though 1 died two months later of sepsis.

TABLE 1 Operative Procedures on 63 Patients

| OPERATIVE PROCEDURE | No. of Times Performed |
|--|------------------------|
| Exploration, with or without drainage, in non-perforated cases | 12 |
| Exploration and drainage for sudden perforation with peritonitis | 3 |
| Exploration and drainage for slow perforation with abscess | 14 |
| Posterior colotomy for pelvic abscess | 3 |
| Cecostomy | 16 |
| Colostomy (descending colon) | 9 |
| Colostomy (trans cecum colon) | 10 |
| Mikulicz resection | 3 |
| Resection with end-to-end anastomosis | 2 |
| Anterior resection with permanent colostomy | 4 |
| Ileostomy | 3 |
| Exploration with resection of diverticulum | 3 |
| Total | 81 |

neighborhood of the mass, and all the patients recovered. It would appear from these figures that drainage is unnecessary when no perforation is discovered at operation, even though there may be some exudate present. Likewise, in retrospect, a decision not to operate at all would have been proper, although in some cases there was evidently sufficient doubt as to the preoperative diagnosis so that exploration seemed advisable. Those cases of acute diverticulitis, in which by virtue of the fact that the sigmoid lies near or to the right of the midline, a preoperative diagnosis of acute appendicitis is inescapable, demand immediate operation. Unnecessary exploration of uncomplicated cases should, however, be avoidable in most instances.

Sudden Perforation

A sudden perforation into the free peritoneal cavity is much less common than slow perforation. It occurred in only 3 of the 140 cases in this series. All 3 patients were operated on. One died of peritonitis and 1 recovered. The third case in which perforation occurred after exploration, has been mentioned.

Slow Perforation with Abscess

In another group of 14 cases, abscesses developed from slow perforation and were explored and drained through the peritoneal cavity, with a high mortality. Seven patients died in the hospital of peritonitis, while 7 recovered. One of the

CHRONIC OBSTRUCTIVE DIVERTICULITIS

Recurring attacks of acute inflammation in the same area eventually build up a chronically inflamed, thickened segment of bowel, which never returns to normal between the episodes. A narrowing of the lumen is continually present, though it may not be obvious on a liquid or low residue diet except during the exacerbations of inflammation. The sigmoid may have become adherent to the bladder during one of these attacks, with or without the formation of a fistula, if a fistula is present, the subsequent attacks are associated with dysuria and frequency, and also with pneumaturia. Fistulas may develop between the colon and the small bowel, rectum, vagina or abdominal wall. In this series there were 4 cases with vesicocolic fistulas, all operated on more or less successfully by multiple stages. One nephrocolic and 1 enterocolic fistula occurred, the former patient dying without operation, the latter after attempted repair.

Indications for Colostomy

Not infrequently, individuals develop intestinal obstruction to a degree which necessitates surgical relief by colostomy. In such cases it is often difficult to be certain whether one is dealing with cancer or diverticulitis, not only prior to operation but also after the abdomen has been opened. Regardless of whether the incision has been made on the right or left side, exploration is likely to be difficult because of distention. The differential diagnosis frequently cannot be made by palpation of the mass and often is in doubt even when the mass is visualized. Furthermore, it is frequently undesirable even to attempt exploration of the mass in the presence of marked distention.

Diversion of the fecal stream will cause the diverticulitis to quiet down in all cases, but the chronic obstructive process never can return to normal, and subsequent closure of the colostomy

is likely to produce a recurrence of the trouble. In one of our cases a barium enema fifteen months after colostomy revealed little or no reduction in the narrowing, closure, despite this fact, resulted in death of the patient from peritonitis.

Indications for Resection

There are several factors justifying radical surgery in an increasing number of cases of chronic diverticulitis. These are recurring obstruction and fistula formation, the possibility of perforation during further acute attacks, and the ever-present possibility that the obstruction may actually be due to cancer rather than diverticulitis, or to a co-existence of both conditions. The ability of a good radiologist to differentiate the two lesions by detecting the loss of mucosa due to cancer is a great help to the surgeon in deciding for or against operation.

TYPES OF OPERATIVE PROCEDURE

Since obstruction occurs almost invariably in the sigmoid — usually in its upper part — and since it seldom involves over 10 cm of bowel, it is possible in most cases to resect this segment and restore continuity, though a permanent colostomy will be necessary in some. Because of the inflammatory thickening of the mesosigmoid, which is often more prominent than is the thickening of the bowel itself, resection is more dangerous than in the case of cancer and should rarely be carried out as a single-stage procedure. A colostomy should precede resection.

Cecostomy, which diverts very little fecal material, is indicated only as the simplest method of relieving complete obstruction in a sick patient. It was performed in 16 cases in this series, with 1 death from peritonitis. In a number of these cases other procedures were also carried out, either before or after cecostomy.

Colostomy using the descending colon is ill-advised if future resection is contemplated, because the opening is situated too near the area of the second operation. Nevertheless, the descending colon was utilized in 9 cases in the series, with no operative mortality.

Complete diversion of the bowel contents is best accomplished by colostomy in the transverse colon, with section of the bowel. The two ends can be constructed for later closure either by the Mikulicz or the Devine method, the former being simpler, and probably just as efficient as the latter. Transverse colostomy was performed in 10 of our cases, with 1 death from pneumonia.

After several weeks' interval during which the defunctioned distal bowel is washed out daily, the obstructing segment can be resected and conti-

nunity re-established either by the Mikulicz method or by end-to-end suture, using basting stitches or an anastomosis clamp such as that devised by Young.* In a bowel cleaned out for several weeks, an open anastomosis can probably be done successfully, though the so-called "aseptic" methods are safer. A short, thick mesocolon, such as that found so often in heavy-set individuals, with its thickness increased by the chronic inflammation of diverticulitis, does not usually lend itself to a Mikulicz resection since the bowel is also short. Under these circumstances an end-to-end anastomosis is the only feasible procedure short of permanent colostomy.

In the Massachusetts General Hospital series, Mikulicz resection of the sigmoid was performed in 3 cases, all with good results. End-to-end suture was carried out in 2 cases, also successfully. Anterior resection, with a permanent colostomy and inversion of the rectal stump, was performed in 4 cases, with 2 hospital deaths from sepsis. Inversion of the stump is technically difficult as a rule, and if the stump is short it may not be possible to leave the inverted end within the peritoneal cavity without drainage, which is the best way to handle it. If the stump slips below the peritoneum, drainage should be carried out through the vagina or beside the coccyx, but even so, fatal retroperitoneal sepsis may occur.

Since it is impossible to know in advance which of the above procedures will prove to be best, and since resection with end-to-end suture without preliminary defunctioning of the left colon is risky, it is evident that a colostomy in the transverse colon should precede all resections of the left colon for diverticulitis and all attempts to disconnect and repair fistulas resulting from perforation.

Ileostomy was performed in 2 cases of the series, in one for gangrenous diverticulitis of the cecum and in the other to permit closure of a badly broken-down cecostomy stoma. Resection of a single diverticulum was carried out in 3 cases. Eighty-one operative procedures were performed in 63 patients.

END RESULTS

I have been able thus far to secure adequate end result data on 44 of the 77 unoperated cases and on 49 of the 63 operated cases, a total of 93 patients.

Of the 44 unoperated cases, 3 patients died in the hospital, and 14 died later. It developed that 2 of the latter group had cancer of the sigmoid as well as diverticulitis. In the other 12, death was also due to causes other than diverticulitis. Twenty-seven patients have remained alive for

*Young, E. L., Jr. A new instrument for intestinal anastomosis. *New Eng J Med* 206:943-945, 1932.

various periods of time, 19 without symptoms and 8 with recurring attacks.

Of the 49 operated cases followed, 28 patients died. Sixteen of these died in the hospital. Of the 12 subsequent deaths, 5 were due to what was reported to be cancer of the colon,—though this was not proved in every case,—4 to complications of the diverticulitis and 3 to unrelated causes. Twenty-one patients were still living, 5 with recurrent symptoms of diverticulitis and 16 apparently free from symptoms. Of the entire group of cases, 31 had only one operation while 18 were subjected to two or more surgical procedures.

CONCLUSIONS

Acute diverticulitis is always a nonsurgical problem unless perforation makes operation necessary.

Immediate operation is essential in a sudden acute perforation, while delayed operation is preferable in a slow perforation with abscess.

Chronic obstructive diverticulitis, with or without fistula formation, though relieved by complete diversion of the fecal contents, is likely to recur if the colostomy is closed. Resection, when the left colon has been rendered clean following colostomy, is a relatively safe procedure, and is usually indicated in these cases.

770 Commonwealth Avenue.

DISCUSSION

Dr. JOHN HODGINS, Boston. There is one aspect of this subject which I should like to speak of and that is the type of infection which is apt to spread especially into the retroperitoneal tissues. The effect is exceedingly dangerous and often fatal. Moreover, the intestinal bacteria may include the gas-forming organisms and at the Peter Bent Brigham Hospital several years ago a surgeon, in exploring a thickening not known to be due to diverticulitis,

examined and lifted the adherent sigmoid. In consequence the instruments became contaminated with the gas bacillus, and the patient and two others died before anyone suspected the possible presence of these bacteria. Of course ordinary scrubbing and boiling had failed to destroy their spores on the instruments.

Dr. WILLIAM C. QUINBY, Boston. A point which I think is worth noting in regard to those communications which sometimes occur as a result of perforation of a diverticular abscess into the urinary bladder is that in the majority of cases the opening formed is so small that it is rather hard to find by cystoscope as a result, the infection is usually not one which causes a great deal of bladder dysfunction—not much pain and frequency of urination, but nevertheless a persistent pyuria.

In the cases which have been spoken of as showing pneumaturia and so forth the communication into the bladder is usually in my experience, the result of an intestinal cancer rather than simple peridiverticular abscess. In these cases the area of the perforation into the bladder is much more readily seen through the cystoscope than it is in cases of the former type.

Dr. THOMAS H. RUSSELL, New Haven, Connecticut. It happens that I have 2 cases at the present time in which an intestinal resection has been done for diverticulitis. One is that of a woman of sixty-six who had a series of x-ray films taken eighteen months before which showed diverticula. She had an acute flare-up a few months before, and twenty-four hours before I saw her had an acute attack of vomiting. The leukocyte count was 23,000 and a mass was made out in Douglas's cul-de-sac. An operation was done ten days ago through a low midline incision. From the earlier x-ray films it was evident that the diverticula were very low. The upper portion of the rectum and the lower sigmoid were infiltrated with pus and the patient was very sick. I was able to deliver the inflamed loop, part of which was gangrenous. The patient is now making normal progress.

Three days ago I saw a man of sixty-seven who had had intermittent attacks of partial obstruction. It was decided to operate on him. A Mikulicz operation was more easily done in this case because the involved portion of the intestine was the sigmoid. I removed the loop of intestine yesterday and anticipate a smooth convalescence.

These two cases which were resected have been the only ones in which I thought it necessary to do a radical operation the others being treated conservatively or by simple drainage.

ANTEPARTUM GAS-BACILLUS INFECTION¹Report of a Case with Septicemia and Recovery
But with Death of the FetusSAMUEL A. COSGROVE, M.D.,[†] AND THOMAS A. BARRY, M.D.[‡]

JERSEY CITY, NEW JERSEY

THE presence of *Clostridium welchii* in the genital tract is not uncommon. While all true strains of *Cl. welchii* are probably pathogenic, the presence of this organism does not necessarily signify infection, because Schottmüller¹ found it in the vaginas of healthy women. Certain prerequisites are necessary for pathogenicity, namely trauma and tissue necrosis. Falls² noted the presence of *Cl. welchii* in 63 per cent of a large series of prenatal patients. At the Sloane Hospital in New York City, Bysshe³ reported *Cl. welchii* in 25 out of 547 antepartum and postpartum patients, an incidence of 4.5 per cent. Of the 25 cases, 1 patient died presenting the typical picture of gas-bacillus sepsis, and 5 developed puerperal endometritis in which the only organism found was *Cl. welchii*. Peckham⁴ in his study of 545 patients ill with puerperal infection found the organism in only 0.6 per cent of those cultured.

Cl. welchii is probably present in a larger number of infected cases than one realizes, and apparently is not at all times an organism of high virulence but only when circumstances are favorable. If it were virulent, undoubtedly there would be far more deaths attributable to such infection.

In 38,330 deliveries at the Margaret Hague Maternity Hospital, only 3 cases have been definitely diagnosed as complicated by *Cl. welchii* infections. In 1934 a patient had an intrauterine *Cl. welchii* infection diagnosed at delivery of a full-term baby. The patient had been seen by a midwife, who examined her several times vaginally at home. She was treated with serum and recovered. In 1935 another patient entered the hospital with a high temperature, was delivered of a stillbirth and died of a pelvic gas bacillus infection within twenty-four hours. In the recovered case reported herewith the patient was proved to be infected systemically and locally with virulent *Cl. welchii*. There may have been other cases in which *Cl. welchii* was a factor in morbidity, but no other characteristic case in either mother or child has been noted. This fact, to-

gether with the known incidence of *Cl. welchii* in the flora of the birth tract, noted above, excites speculation as to the virulence of the organism and the conditioning factors.

We know that the organism is essentially a saprophyte, becoming pathogenic only when introduced into a tissue medium that fulfills the necessary prerequisites, that is, consists of tissue which is devitalized, dying or necrotic. De Kruif, Adams and Ireland⁵ and De Kruif and Bollman⁶ have amply demonstrated that the spores or vegetative organisms thoroughly washed free of toxin are far less virulent than are equal numbers of organisms not separated from the toxin. The primary conditions for infection are usually established by tissue damage resulting from wounds, areas of necrotic tissue furnish a favorable medium for the growth of the organism, making it possible for the bacilli to produce toxin, which eventually leads to toxemic injury and death.

In 49 cases with an abnormal pregnancy, labor or puerperium, Wrigley⁷ found *Cl. welchii* in the lochia of 13 patients and drew the conclusion that this organism is usually exogenous. He postulated the following conditions as necessary in order to have severe maternal infection: the organisms must be introduced into the uterus, they must find there suitable "dead" material—the fetus—on which to grow, the dead fetus must remain in utero a sufficient time for active infection to begin, and damaged maternal tissues must be exposed to this infection.

Another factor may be added: the presence of other organisms that affect the virulence of *Cl. welchii*. Lash⁸ reports that the pathogenicity can be considerably increased if the organism is growing in the presence of *Streptococcus haemolyticus*. As this has been confirmed by Falls,² we must be a little more guarded as to prognosis if the flora of the birth tract in a case of gas-gangrene infection also contains *Str. haemolyticus*.

CASE REPORT

D. M. (No. 38330), aged 19, was a primiparous white woman whose last menstrual period began December 27, 1938, and whose expected date of confinement was September 29, 1939. She entered the hospital June 28, with

*From the Obstetrical and Bacteriological departments of the Margaret Hague Maternity Hospital, Jersey City, New Jersey.

†Medical director and superintendent, Margaret Hague Maternity Hospital, Jersey City, New Jersey; clinical professor of obstetrics, Columbia University College of Physicians and Surgeons.

‡Resident gynecologist, Harlem Hospital, Department of Hospitals, New York City; formerly director of the Clinical Laboratory, Margaret Hague Maternity Hospital.

a history of irregular, cramp-like pains of 15 hours duration the membranes had ruptured 10 hours previously. The first trimester of pregnancy had been uneventful. The patient had noticed a sudden gush of blood not associated with any pain at about the end of the 3rd month. She had continued spotting for a few days after which the bleeding ceased.

Physical examination revealed a well-developed and nourished white woman in labor. The heart rate was 80, regular and of good quality. A harsh blowing systolic murmur was heard over the pulmonary area. The blood pressure was 118/70. The lungs were resonant throughout. The uterus was enlarged to 22 cm. above the symphysis, and the fetal heart could be heard in the midline, with a beat of 136, regular and of good quality. The presenting parts could not be identified abdominally. Rectal examination revealed the cervix to be effaced but not dilated and the vertex presenting. The temperature was 98.6 F, the pulse 80, and the respirations 20. The diagnoses were pregnancy 24 weeks, and inevitable abortion.

The labor pains gradually diminished but did not cease. The fetal heart weakened. The following day the temperature rose to 100.6 F. The intrapartum course was uneventful until June 30 when the labor pains increased to every 2 or 3 minutes. The cervix admitted 1 finger and no fetal heart could be heard. The membranes had been ruptured for 52 hours and the vaginal discharge, which had previously been clear, turned yellow and cloudy later becoming green and foul. The temperature gradually rose to 101.6 F., the pulse to 116, and the respirations to 26. The patient was taken to the delivery room at 10 p.m. with the caput showing, and delivered spontaneously a stillborn girl with obvious subcutaneous crepitation all over the body. No maceration was noted but the skin showed several large, reddish-blue areas. Cervical cultures were taken, and these, together with fetus and placenta were sent to the laboratory where smears were made from an incision in the muscles of the back of the fetus, which had a "cooked-meat" appearance. Microscopical examination revealed large gram-positive bacilli. The placenta showed two areas at the periphery 2 by 3 cm. in diameter which were fibrous and grayish white. The patient had a chill 1 hour following delivery, and blood was withdrawn 45 minutes later for aerobic and anaerobic cultures.

The anaerobic blood culture and cervical culture revealed marked gas formation after 10 hours growth. The organisms were large gram-positive, non-motile bacilli (Fig. 1). Rabbits injected intravenously with organisms from the blood and cervical anaerobic cultures and killed in 10 minutes were blown up with gas after 6 hours incubation. A guinea pig was injected with the organism cultured from the patient's blood. This pig died within 23 hours with evidence of gas in its tissues from which pure cultures of large gram-positive bacilli were recovered. A second pig was injected with the identical amount of culture and at the same time as the first pig but also received simultaneously a dose of polyvalent gas-gangrene antitoxin. This pig was alive and well in 24 hours and remained so. Since *Cl. welchii* is the only organism of the pathogenic group of gram-positive spore-bearing bacilli that is non-motile, and since it was obvious that the organism had killed the first guinea pig, we believe that this patient had a *Cl. welchii* septicemia. However further bacteriological studies were carried out with the following results: dextrose, lactose and saccharose were fermented with the formation of acid and gas; salicin was not fermented; there was no liquefaction of coagulated blood serum and gelatin was liquefied. Cultures of the organisms from

the patient's blood stream and from the guinea pig in litmus milk showed stormy fermentation. All the reactions were typical and conclusive proof of the presence of *Cl. welchii*. Blood cultures taken 24 hours later revealed no growth. Anaerobic cervical cultures taken every other day to July 8 yielded *Cl. welchii*. The next three cultures were negative.

Immediately following delivery a prophylactic dose (>500 units) of combined tetanus and gas-bacillus antitoxin and 4 gm of sulfanilamide were given. One gram of sulfanilamide and 1 gm. of soda bicarbonate were ordered every 4 hours. One hour later the patient had a chill the temperature rising to 104.0 F., and the pulse to 140 following which her condition seemed fairly good. A therapeutic dose (23,700 units) of polyvalent gas-bacillus antitoxin was given intravenously 3 hours after the first dose. A third and last injection (23,700 units) of antitoxin was administered 9 hours after the initial dose.

The sulfanilamide dose per day was raised in 24 hours to 6 gm. and continued from July 1 to July 8 it was then diminished to 2 gm. for 2 days and was stopped. The

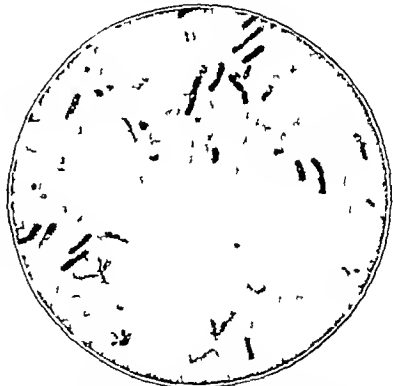

FIGURE 1 Smear from Anaerobic Culture of the Patient's Blood Showing Heavy Growth of *Cl. welchii*

blood sulfanilamide was between 8 and 9 mg. per 100 cc. until the dose was diminished, when it fell to about 5 mg. During the treatment with sulfanilamide, the patient developed a cyanosis. No evidence of jaundice or of hematuria was ever noted. The red-cell count varied between 4,400,000 and 3,575,000 and the hemoglobin from 88 to 70 per cent during the course of drug treatment. The white-cell count the day after delivery was 25,000 subsequently falling to 18,800.

The postpartum course was uneventful, except for an afternoon temperature rise to 99.5 or 101.0 F for approximately two weeks. The patient never appeared toxic or felt ill. The uterus involuted properly. She was discharged on July 16 to return in 2 weeks for a checkup at which time a cervical culture revealed suspiciously large gram positive bacilli but anaerobic culture failed to yield *Cl. welchii*.

The sequence of events relative to fetal and maternal infection in this case is of interest. It is

probable that organisms already present in the vagina ascended to the uterus or were carried there during intercourse, douching, bathing or frequent rectal examinations. Did the organisms go from the uterine cavity into the fetus with subsequent production of gas gangrene, or did they

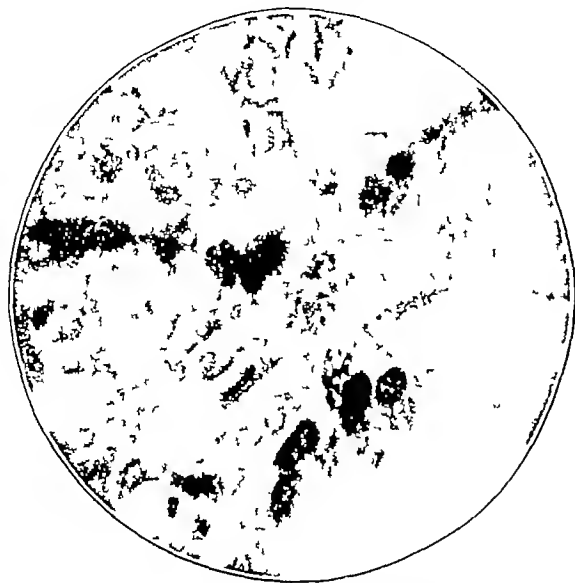

FIGURE 2 A Section of the Placenta Showing *Cl welchii* in the Intervillous Spaces

invade the placenta and thence the fetal circulation? Granting the possibility of the first sequence of events, we think the latter more probable.

The placenta revealed several areas near the

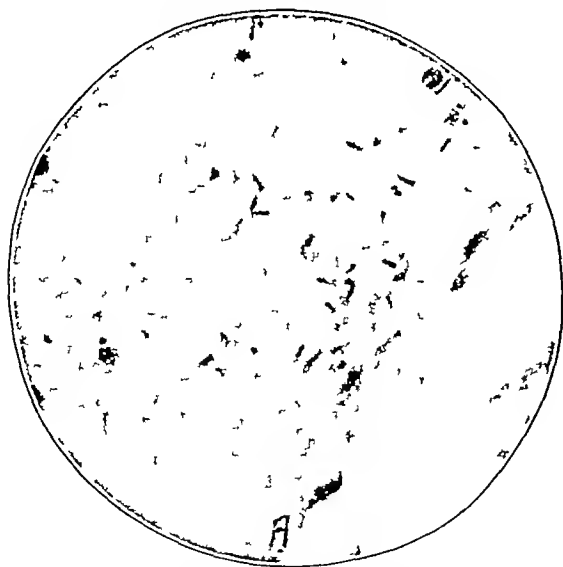

FIGURE 3 A Section of the Fetal Kidney Showing *Cl welchii* in the Lumen of a Small Artery
A indicates the wall of the artery

periphery that were white and firm. Specially stained sections of these areas revealed the presence of *Cl welchii* in the intervillous spaces (Fig 2). The organisms present in the uterine cavity

probably wandered in, invaded the dead tissue, grew and penetrated the placenta and thence the general fetal circulation (Fig 3), with subsequent death of the fetus. The fetal heart sounds were not obtained six hours before delivery, long enough for the classic picture of gas gangrene to develop before extrusion of the fetus.

If invasion was through the placenta with subsequent fetal death, it is reasonable to assume that the mother was infected at the same time, but evidence of severe infection did not develop until two hours after delivery and eight hours after the fetal death. The organisms present in great numbers in the infected endometrial cavity probably invaded the blood clots in the sinuses immediately after delivery, and from there found their way into the maternal blood stream. The mother had no chills prior to delivery, nor did her temperature reach its peak until she had the chill two hours post partum. This sequence of events would seem to suggest that spread of the infection was from the uterine cavity into the fetus ante partum and from the uterine cavity into the maternal circulation post partum.

The treatment of *Cl welchii* infection in general has seen a change during the last two decades from entire reliance on radical surgery to a more conservative form of therapy, with improved results. To surgery has been added serotherapy, at one time an adjuvant, but now on an equal status. Both have recently been complemented by a new agent, sulfanilamide.

Since most obstetric infections are intrauterine, surgery has always represented a hazardous and limited method of therapy. Obstetricians were forced to use conservative methods. Treatment with serum has had fair results, sulfanilamide now promises better ones. Bates,⁹ reviewing the cases of gas gangrene in a large surgical series, from 1926 to 1932, observed that the mortality was 56 per cent, equal to that of the World War period. In this series, the use of serum received but slight attention. Elason, Erb and Gilbert,¹⁰ reviewing the literature from 1930 to 1936, give the following figures: of 224 patients treated with serum, 56 died, a mortality of 25 per cent, and of 125 patients not treated with serum, 62 died, a mortality of 49 per cent. Millar's¹¹ statistics also showed a fall in mortality from 43 to 38 per cent following the use of serum. These figures indicate that serum has appreciably lowered the mortality.

Bohlman¹² reported dramatic results in a case of *Cl welchii* infection from the use of sulfanilamide. The patient had received a prophylactic dose of gas-bacillus antitoxin, but later developed gas gangrene in the lower extremities, for which sulfanilamide was given. It seems necessary to

assume some secondary therapeutic activity of the drug, besides the direct action, because Spray¹³ showed in vitro that *Cl welchii* is scarcely affected by any concentration approaching that tolerated in man.

This patient was treated energetically with both serum and sulfanilamide. Prostration, high fever, abdominal pains and vomiting were absent, although cyanosis was present. Since she received a large amount of sulfanilamide, it is hard to say whether part of the early cyanosis was caused by the infection or by the drug. She never appeared or felt sick during the entire stay in the hospital.

SUMMARY AND CONCLUSIONS

Clostridium welchii is an organism that will not cause damage unless the conditions are suitable. Once growth starts, the disease is not self limiting. As the toxins are liberated and more tissue is devitalized, the infection becomes greater. The uterus is a perfect incubator, the dead fetus an excellent medium. Since there is no way of telling whether the dead fetus is infected, one is forced to await the outcome of a delivery before making a diagnosis.

Surgery has no definite place in the therapy of obstetric gas-gangrene infection, because the uterus is not properly situated for surgical attack. Obstetricians are thus limited to conservatism. Antitoxin has proved its worth to some extent. Sulfanilamide seems also to have value. The combination of both appears to be the ideal method

of therapy, the drug producing bacteriostasis, and the antitoxin, neutralization of the toxin.

Although each form of therapy has been shown to be curative, it cannot be proved which exerted the greater effect in this case, because both forms were given at the same time and were continued. This case clearly showed that the desired effect can be obtained by combined therapy, because the patient did not develop any of the most distressing of the characteristic symptoms of *Cl welchii* infection. We believe that this form of therapy will do much toward lowering morbidity as well as mortality.

symptoms. The dietetic treatment of moderately severe cases consists in the use of a diet low in carbohydrate, high in fat and normal in protein and frequent feedings.³ This case of the severe type was treated with diet and gland therapy with marked improvement. There is an advantage in using low percentage fruits and vegetables, since their slow digestion yields only small quantities of glucose at a time, by which process the minimum stimulation of insulin is brought about. Fats, in the form of milk and cream, given with and between meals, are believed to delay assimilation of the carbohydrates by allowing the stomach to empty slowly.⁴ Mixed gland therapy is recommended when the attacks cannot be controlled by diet.⁵ Operation on the pancreas is justified in cases in which there is a constant uncontrollable tendency for the blood sugar level to fall below 50 mg per 100 cc., thus preventing the patient from earning his living.⁶

To bring a patient out of an attack when he cannot co-operate by swallowing sugar syrup or

sweetened orange juice, intravenous injections of glucose must be given. Adrenalin, pituitary extract and thyroid substance have also been used.

The prognosis is usually favorable since in the majority of cases the state is purely functional, with no organic lesion in the pancreas or other glands of internal secretion.

SUMMARY

A case of the severe type of hyperinsulinism is presented and briefly discussed.

866 County Street.

REPORT ON MEDICAL PROGRESS

CHILDREN'S SURGERY

WILLIAM E. LADD, M.D.*

BOSTON

APPENDICITIS

APPENDICITIS continues to claim consideration, since it remains a factor of major importance in childhood mortality. Better nutritional standards and more effective public health measures have resulted in a lowered child mortality rate, so that more children are saved from other diseases to suffer from, and all too frequently to die of, appendicitis. The annual number of child deaths from appendicitis has declined but little and the child population appears, temporarily at least, to be stabilized. The general death rate in Massachusetts per 10,000 children under ten years of age was 669 in 1920, 324 in 1930 and 180 in 1936, but the rate for children with appendicitis was 8.2 per cent in 1920, 15.9 per cent in 1930 and 10.6 per cent in 1936†. Only pneumonia and accidents exceed appendicitis as a cause of death in this age group.

Unfortunately, the idea remains fixed in the

public mind that the young need not be suspected of appendicitis and, more unfortunately, there is reason to suppose that some physicians fail to consider such a diagnosis early in the course of an attack.

Certain facts are established. Appendicitis occurs in the young with reasonable frequency, and is a killing disease if not recognized and treated promptly. There is no nonsurgical method of treatment of merit. Operation before peritoneal infection is present is absolutely curative, with essentially no surgical risk. When properly managed the young are excellent anesthetic and surgical risks, but they must be well managed.

Considering these facts, control of morbidity and mortality can be reduced to three elements: first, the public must realize that a physician should be called promptly whenever there is a complaint of abdominal pain; second, physicians must become appendix-conscious and really examine the child patient; and third, appendectomy must be performed expeditiously if a diagnosis is established and such operation should be considered seriously if appendicitis cannot be excluded from

*Chief of the Surgical Service, Children's Hospital, Boston; clinical professor of surgery Harvard Medical School.

†These statistics represent calculations by Dr. H. W. Hudson, Jr., from material submitted by the Massachusetts Department of Public Health, and refer to conditions in Massachusetts only.

diagnosis. If these conditions were fulfilled there would be no appendicitis problem. Until a level of education is reached which attains these three elementals, both long periods of morbidity and deaths will result from peritonitis of appendiceal origin. It is my considered opinion that discussion of treatment of the desperately ill patient should be confined to surgical meetings and surgical literature. I believe that open discussion of methods which are still matters of surgical opinion has resulted in harm, in that it may have given rise to the entirely erroneous idea that there is both a medical and a surgical method of managing appendicitis. *There is no medical treatment.* The questions of delayed operation with Ochsnerization (with its modifications), drainage versus no drainage, enterostomies of various types, serotherapy, chemotherapy, the use of coli-bactrogen, types of incision used to approach an appendix, and the time at which to approach it, and the use of drugs to maintain intestinal tone or stimulate peristalsis will not be discussed here.

Decompression of the intestine by means of Wangenstein's¹ technic, lessening of distention by the use of an atmosphere of high oxygen tension, as recommended by Fine, Hermanson and Frehling,² the control of hydration, the maintenance of blood-electrolyte levels, the prevention of ketosis by parenteral fluid administration and the use of blood transfusion for low serum-protein levels are all advances of proved merit in the control of the desperately ill.

Real progress will be made when children are referred for surgery earlier in the course of their disease. In this connection the lowering of mortality in the Children's Hospital series of cases of proved acute appendicitis with and without complications is encouraging. For the period 1929-1938 the death rate was 3.06 per cent, for 1929-1933 it was 3.6 per cent, for 1933-1938 it was 2.3 per cent, and for 1938 and 1939 it was 2.2 per cent.³ Although improved methods play a leading role in this reduction, the fact that fewer patients presented peritoneal complications was also significant. This, we believe, represents progress in the control of appendicitis mortality.

EMPHYEMA

The treatment of acute empyema, especially in children, has received much discussion since the war. The three forms of treatment—repeated aspiration, intercostal closed drainage and open drainage, with or without rib resection—have each had their strong proponents and opponents. It is becoming more widely appreciated, however, that each of these methods has its usefulness, its indi-

cations and its contraindications. It is fundamental to realize that each patient must have that form of treatment that is best suited to the etiologic organism, the stage of the disease and the age of the patient. The improvement in the results during the last five years at the Children's Hospital⁴ was effected largely because no routine form of treatment was used. One, two or all three forms of treatment have been used as the individual case warranted.

Acute empyema should never be regarded as a surgical emergency but rather as a complication of an acute primary disease. Diagnostic aspiration is important in all cases, and methods of drainage should be based on the bacteriological findings as well as on the stage of the disease and the age of the patient. During the pneumonic stage treatment should be instituted only when necessary in order to relieve the mechanical embarrassment of the heart and lungs, and then only by repeated aspiration or occasionally by closed drainage. Open drainage should never be done in the pneumonic stage. In properly selected cases, however, primary rib resection is a rapid and efficient method of treatment, and it is also useful as a secondary procedure when intercostal drainage has proved inadequate. Local anesthesia for aspiration and intercostal drainage, and nitrous oxide and oxygen for open drainage, are favored. Scoliosis need not be feared if the cavity is well drained and the lung re-expanded. By following these principles the mortality has been reduced in the last five years to 2 per cent in 137 cases. The mortality in patients under two years of age was reduced to 4 per cent in 46 cases.

CHRONIC PULMONARY SUPPURATION

Chronic suppurative lesions of the lungs in children can be treated successfully by radical lobectomy or pneumonectomy, and these radical procedures should not be withheld on account of the age of the patient. Although the causative agent in many cases of pulmonary chronic suppuration is obscure, prevention is of course far better than treatment after suppuration has occurred. Particularly in this age group the possible presence of a foreign body must always be considered and ruled out in any case of infection of the lung that does not respond to the usual therapy. The presence of an atelectatic lobe in recurrent pneumonia must also be considered as an underlying cause of chronic suppurative disease in the lung. In many cases, chronic lung suppuration that follows acute empyema can probably be avoided by adequate treatment of the empyema during its acute stages. There remain other cases for which no definite etiology has as yet

been found. These cases need careful bacteriological study and the closest observation, including repeated x-ray photographs after injection of Lipiodol. If, after a varying period of weeks, the process shows no signs of improvement, radical removal of the diseased portions of the lung must be considered. With too long a delay the process may go on to gangrene and so preclude successful radical removal. It is difficult as yet to assign any absolute time limit at which radical treatment should be instituted.

At the Children's Hospital there have been 14 lobectomies performed for chronic lung suppuration, with no deaths. There have been 6 total pneumonectomies, with 2 deaths. One of these deaths might have been avoided had radical surgery been done at an earlier stage of the disease.

DUPLICATION OF THE ALIMENTARY TRACT

Duplication of the alimentary tract is a term which has been used to describe a condition which has heretofore received a variety of titles, none of which are both accurate and inclusive.

Pathology

Duplications of the alimentary tract are hollow structures which possess two muscular coats and are lined by epithelium similar to that found in various segments of the gastrointestinal tract. These lesions are almost always contiguous to some portion of the alimentary tube. The type of epithelium lining the duplication does not necessarily correspond to that part of the alimentary tract to which the structure is attached. The cystic structure may or may not communicate with the adjacent intestinal lumen.

An important finding is the histological fact that the muscular coats of the duplication are intimately associated with or are an integral part of the muscularis of the alimentary tract.

The contents of the duplication vary with the type of epithelium lining the structure, with the presence or absence of a communication of the adjacent intestine and with the presence or absence of necrosis of the duplication wall. If there is a communication with the bowel, the duplication contents naturally are similar to those of the adjacent bowel. If there is no communication the contents usually contain a clear colorless fluid of mucoid consistency.

Clinical Findings

This condition is usually observed in children. The symptoms may be grouped under three headings: obstruction of the alimentary tract by regional external pressure, pain produced by distention of the cystic structure and hemorrhage be-

cause of interference with the intestinal blood supply, leading to sloughing of the intestinal mucosa.

Duplications may occur at any point from the mouth to the rectum, and the symptoms, of course, vary with the location of the condition. In a lesion appearing at the base of the tongue, difficulty in swallowing was the outstanding symptom in this series. With the duplications in the mediastinum, difficulty in swallowing and interference with expansion of the lung leading to dyspnea were the prominent symptoms. In a duplication of the stomach, the symptom was that of epigastric fullness and pain, produced by tenseness in the mass. Most of the cysts of the duodenum, jejunum and ileum brought early signs of partial intestinal obstruction characterized by colicky pain, vomiting, increased peristalsis and finally signs related to dehydration. In a duplication of the terminal ileum, the complaints were related to severe painless hemorrhage from the lower intestinal tract caused by ulceration and sloughing of the ileal mucosa. In one case the duplication of the ileum was the advancing point of an intussusception and gave the usual symptoms of that condition. The duplication of the rectum caused early constipation and abdominal distention.

By physical examination these masses can usually be felt and a correct diagnosis is often suggested. The tumors were elastic, usually non-tender and well rounded, and except for the duodenal lesion, were quite freely movable within the abdominal cavity. Intestinal duplications all showed signs of partial intestinal obstruction, such as visible peristalsis, localized abdominal distention and increased audible peristaltic activity. The cyst of the rectum could be easily palpated by rectal examination, and was sufficiently large so that the examining finger could not be pushed beyond the compressed point.

Treatment

The structure of these lesions is important in relation to operative procedures. First, the cyst and the intestine have a common wall and the two cannot be dissected apart with safety. Second, an attempt to remove the cystic structure locally may interfere with the blood supply of the intestine and cause necrosis.

The thoracic lesions may present great difficulty, particularly in the very young. Freeing the cystic structure from the lung is comparatively simple, but when one attempts to dissect it from the esophagus there is danger of entering the esophageal lumen, and the possibility of a fatal mediastinitis or an empyema or an esophageopleural fistula is great. As a result of my experience, I believe that these cases are better treated

diagnosis. If these conditions were fulfilled there would be no appendicitis problem. Until a level of education is reached which attains these three elementals, both long periods of morbidity and deaths will result from peritonitis of appendiceal origin. It is my considered opinion that discussion of treatment of the desperately ill patient should be confined to surgical meetings and surgical literature. I believe that open discussion of methods which are still matters of surgical opinion has resulted in harm, in that it may have given rise to the entirely erroneous idea that there is both a medical and a surgical method of managing appendicitis. *There is no medical treatment.* The questions of delayed operation with Ochsnerization (with its modifications), drainage versus no drainage, enterostomies of various types, serotherapy, chemotherapy, the use of coli-bactrogen, types of incision used to approach an appendix, and the time at which to approach it, and the use of drugs to maintain intestinal tone or stimulate peristalsis will not be discussed here.

Decompression of the intestine by means of Wangenstein's¹ technic, lessening of distention by the use of an atmosphere of high oxygen tension, as recommended by Fine, Hermanson and Frehling,² the control of hydration, the maintenance of blood-electrolyte levels, the prevention of ketosis by parenteral fluid administration and the use of blood transfusion for low serum-protein levels are all advances of proved merit in the control of the desperately ill.

Real progress will be made when children are referred for surgery earlier in the course of their disease. In this connection the lowering of mortality in the Children's Hospital series of cases of proved acute appendicitis with and without complications is encouraging. For the period 1929-1938 the death rate was 3.06 per cent, for 1929-1933 it was 3.6 per cent, for 1933-1938 it was 2.3 per cent, and for 1938 and 1939 it was 2.2 per cent.³ Although improved methods play a leading role in this reduction, the fact that fewer patients presented peritoneal complications was also significant. This, we believe, represents progress in the control of appendicitis mortality.

EMPHYEMA

The treatment of acute empyema, especially in children, has received much discussion since the war. The three forms of treatment—repeated aspiration, intercostal closed drainage and open drainage, with or without rib resection—have each had their strong proponents and opponents. It is becoming more widely appreciated, however, that each of these methods has its usefulness, its indi-

cations and its contraindications. It is fundamental to realize that each patient must have that form of treatment that is best suited to the etiologic organism, the stage of the disease and the age of the patient. The improvement in the results during the last five years at the Children's Hospital⁴ was effected largely because no routine form of treatment was used. One, two or all three forms of treatment have been used as the individual case warranted.

Acute empyema should never be regarded as a surgical emergency but rather as a complication of an acute primary disease. Diagnostic aspiration is important in all cases, and methods of drainage should be based on the bacteriological findings as well as on the stage of the disease and the age of the patient. During the pneumonic stage treatment should be instituted only when necessary in order to relieve the mechanical embarrassment of the heart and lungs, and then only by repeated aspiration or occasionally by closed drainage. Open drainage should never be done in the pneumonic stage. In properly selected cases, however, primary rib resection is a rapid and efficient method of treatment, and it is also useful as a secondary procedure when intercostal drainage has proved inadequate. Local anesthesia for aspiration and intercostal drainage, and nitrous oxide and oxygen for open drainage, are favored. Scoliosis need not be feared if the cavity is well drained and the lung re-expanded. By following these principles the mortality has been reduced in the last five years to 2 per cent in 137 cases. The mortality in patients under two years of age was reduced to 4 per cent in 46 cases.

CHRONIC PULMONARY SUPPURATION

Chronic suppurative lesions of the lungs in children can be treated successfully by radical lobectomy or pneumonectomy, and these radical procedures should not be withheld on account of the age of the patient. Although the causative agent in many cases of pulmonary chronic suppuration is obscure, prevention is of course far better than treatment after suppuration has occurred. Particularly in this age group the possible presence of a foreign body must always be considered and ruled out in any case of infection of the lung that does not respond to the usual therapy. The presence of an atelectatic lobe in recurrent pneumonia must also be considered as an underlying cause of chronic suppurative disease in the lung. In many cases, chronic lung suppuration that follows acute empyema can probably be avoided by adequate treatment of the empyema during its acute stages. There remain other cases for which no definite etiology has as yet

ures, namely tapping or exploratory burr holes, are necessary becomes increasingly clear as data on these cases accumulate. I am correspondingly less impressed by the lack of history of trauma in these patients. Although parents are carefully questioned on this point, young patients are continually seen with extensive fractures but no history of injury. These fractures have for the most part been seen in otherwise normal bones, and are presumably not due primarily to a deficiency state.

A preliminary survey of the intracranial tumors verified in the Children's Hospital since 1930 shows an interesting pathological distribution. The relative frequency of the various types of tumors in this series does not correspond to those previously reported by others, this difference being of significance chiefly because of the current impression that medulloblastoma is the commonest intracranial tumor of childhood. This impression has, in fact, been advanced as an argument in favor of radiation therapy without exploration, decompression and biopsy. In the series there were 32 astrocytomas and 19 medulloblastomas, a sufficient preponderance of the surgically favorable type to make the supposed high frequency of medulloblastoma an entirely incorrect basis for such therapy. In addition, an analysis of the histories shows that it is frequently quite impossible to make an accurate preoperative pathological diagnosis, preoperative radiation therefore resulting in a very serious loss of time in the less invasive tumors.

The other 35 tumors in the series showed a wide range of cellular structure, from entirely benign dermoid cysts to very rapidly growing invasive tumors, such as glioblastoma multiforme. There were 7 craniopharyngiomas, 1 of which it was

possible to remove in its entirety without residual damage. In the other craniopharyngiomas evacuation of the cyst, with piecemeal and presumably incomplete removal of the wall, had to suffice, but the results even in these cases have been very encouraging. It is obviously essential that these patients receive whatever treatment is possible at an early date before optic atrophy has progressed too far.

It may be worth while emphasizing the fact that children with signs of increased pressure, such as headache, vomiting, papilledema and so forth, or with any disturbance of motor function, except when it is known to be due to a fixed lesion should receive a complete neurological study, and if there is any doubt whatever they should be suspected of having a brain tumor and examined at frequent intervals with that possibility in mind. There is ample proof that many brain tumors of childhood are susceptible of surgical treatment with little or no residual damage if operation is done early enough. In the presence of an operable tumor the removal of which offers a good prognosis, it is therefore extremely important to avoid preliminary trial x-ray therapy or prolonged observation which may leave permanent blindness or motor dysfunction.

CASE RECORDS OF THE MASSACHUSETTS GENERAL HOSPITAL

ANTEMORTEM AND POSTMORTEM RECORDS AS USED
IN WEEKLY CLINICOPATHOLOGICAL EXERCISES

FOUNDED BY RICHARD C. CABOT

TRACY B. MALLORY, M.D., *Editor*

CASE 26091

PRESENTATION OF CASE

A fifty-six-year-old man was admitted to the hospital complaining of painless hematuria.

The patient had enjoyed perfect health until one week before admission when for the first time he passed a large amount of bright-red blood in his urine. Following this he noticed a sharp non-radiating pain in the right flank, which lasted some twenty minutes and disappeared gradually without residual discomfort. He continued to pass blood in decreasing amounts for the next four days. For three days before admission, however, the urine was "dark," but no fresh, bright-red blood was noted. He had experienced no chills, fever, nocturia, frequency, urgency, dysuria or pyuria. He had lost no weight and had noted no other symptoms.

The patient had been in close contact with a brother, who had spent six months of the past year in a local sanatorium because of "weak lungs," and a niece, who had died of tuberculosis eight years before the patient's present illness. The remaining family, marital and past histories were negative.

Physical examination revealed a slender, well-developed man, who lay quietly in bed in no apparent distress. The teeth were carious. Examination of the heart, lungs and abdomen was not remarkable. The genitalia were negative except for the presence of a small, smooth, cystic mass in the globus major of the right epididymis. The rectal examination was negative. The blood pressure was 150 systolic, 80 diastolic.

The temperature, pulse and respirations were normal.

Examination of the blood revealed a red-cell count of 5,300,000 with 177 gm hemoglobin (photoelectric-cell technic), and a white-cell count of 19,000 with 78 per cent polymorphonuclears. The blood smear was negative, the platelets were normal. The urine was cloudy, amber in color and acid, with a specific gravity of 1.016 and a + albumin test. The sediment contained 40 to 150 red blood cells, 5 to 8 white blood cells and 2 epithelial cells per high-power field. The blood Hinton test was negative. The blood sugar and nonprotein nitrogen determinations were normal.

Culture of bladder urine showed a moderate growth of *Staphylococcus aureus* and an abundant growth of nonhemolytic streptococci.

Intravenous pyelograms showed that the kidneys were normal in size, shape and position. There were no visible stones. The intravenous dye appeared promptly and demonstrated normal urinary passages on the left. On the right side there was a sharply defined filling defect occupying the upper major calyx and upper portion of the renal pelvis. The lateral margin of the pelvis in this area showed a slight pressure defect, and there appeared to be slight spreading of the upper and middle calyces. The bladder showed a pressure defect in the region of the prostate. A right retrograde pneumopyelogram confirmed these findings. There was a definite intrapelvic filling defect in the right kidney, which was the same size and shape as that previously demonstrated by the intravenous pyelograms. The margins of this defect were slightly irregular, and it appeared to extend upward along the upper calyx of the kidney. The bladder was not demonstrated.

On the fifth hospital day an operation was performed.

DIFFERENTIAL DIAGNOSIS

DR J. DELLINGER BARNEY: The causes of hematuria are legion and we cannot go into all of them here. When we speak of painless hematuria we usually mean that there are no particular symptoms associated with it. This patient had right flank pain, and there are many causes, of course, for that. But we have to consider the possibility that this man had a tumor in this kidney, the pain being caused not by the tumor but by the formation and passage of large blood clots. Or, he might have had an acute inflammatory disease of the kidney—I refer to carbuncle or multiple cortical abscesses. Or, he might have had a perinephritic abscess, or an acute hemorrhagic nephritis, in which, as Dr. Holmes and I recall very well, the findings may very strongly suggest those of a renal tumor. The fact that he had lost no weight indicates it was not a long-standing process.

His association with two individuals who apparently had tuberculosis might throw some light on the question, but I do not believe it does in this particular case. With the story we have already heard and contact with these individuals, we have to consider the possibility of tuberculosis of the urinary tract. On the other hand, in my experience, renal tuberculosis does not produce massive hematuria or pain, and there is microscopic hematuria rather than gross.

The fact that the temperature, pulse and respirations were normal indicates there was no acute

inflammatory process in the urinary tract. The lungs were said to be negative but that does not absolutely rule out tuberculosis. It comes rather close to it, however. From the description I should think the mass in the epididymis was probably a spermatocele, which occurs not infrequently, is smooth and cystic, varies in size from that of a pinhead to that of an English walnut, occurs in the globus major, and would probably not be confused with epididymal tuberculosis. This might have been a neoplasm of the testicle or the epididymis, but I believe it was a spermatocele. The fact that the rectal examination was negative indicates that there was no obstructing prostate which was large enough to protrude into the rectum. It also suggests that there was no abscess, carcinoma or tuberculosis of the prostate.

Examination revealed that the blood picture was essentially normal. The rather high white-cell count may have been secondary to hematuria or in other words, to the loss of blood. The urine apparently had cleared and was no longer grossly bloody, but the fact that it contained red cells indicates residual blood or persistent, although diminished, hemorrhage. We can rule out any serious inflammatory process by the fact that there were very few white cells in the sediment. Apparently there was very little kidney damage inasmuch as the blood nonprotein nitrogen was normal.

Culture of the bladder urine showed that it did contain bacteria but we not infrequently culture organisms of one sort or another even streptococci or staphylococci, without fever and other clinical manifestations of sepsis. One would have to hunt for the possible focus from which these bacteria came.

The fact that the intravenous pyelogram showed the kidneys normal in size, shape and position tends to eliminate certain things, namely kidney tumors such as hypernephroma or adenocarcinoma, which would probably have caused enlargement of the kidney or an irregularity in its contour where the tumor bulged out from the side. In tuberculosis of the kidney one might not get any particular change. In an inflammatory condition, such as a pyelonephritic kidney, one would find a larger kidney than is normally found. A solitary cyst generally indicates its presence by deformity of the normal kidney outline, but we cannot rule it out. The dye was excreted normally and apparently equally by both kidneys, so that the kidney function was good. In other words, the cortical substance of the kidney had not been badly damaged. But on the right side we find a filling defect occupying the upper major calyx and

the upper portion of the pelvis. This filling defect was found again in the retrograde pyelogram, as we may see in the x ray films. Obviously there was something affecting the pelvis and upper major calyx. The filling defect in the bladder in the region of the prostate may have been due to an enlarged lobe of the prostate. We may see very markedly enlarged prostates at the age of fifty six, but such is not usually the case. The rectal examination is said to have been negative, however, which would be improbable had there been an enlargement of the prostate sufficient to cause a filling defect in the x ray film. The filling defect might have been due to tumor of the bladder or to a blood clot which was lying in the bladder. There are various possibilities.

May I see the x-ray films?

DR. GEORGE W. HOLMES: Apparently we do not have the film that shows the injected pelvis.

DR. OTTO SAHLER: There was only an air injection.

DR. HOLMES: I am glad to know this. I thought I was looking at gas in the colon. You can see the deformity described, also in this film the filling defect and the narrowing of the upper calyx. Of course the patient had been bleeding, and you have to consider the possibility of blood as well as that of tumor. Blood clots as a rule do not extend into the upper calyx without involving the lower calyx. The character of the defect itself is not that seen with blood clot, and we have further evidence of a deformity in a film taken on another day. I think we are safe in saying that it does represent a true lesion in the kidney pelvis. The films do not permit me to say positively that the lesion is a tumor.

DR. BARNEY: As you can see fairly well, the kidney outline is normal in size, without bumps on its contour such as would be expected with a tumor of the cortical substance. But I am interested in this moth-eaten appearance in the pelvis. It looks, in these air injections, as if there was a tongue like process hanging down into the pelvis, and the same tongue like lesion is evidently the dye filled pelvis subsequent to the intravenous pyelogram. You can see it quite definitely in both films, a fact that clearly demonstrates the value of air injection of the renal pelvis. I am not so much impressed with the filling defect in the region of the prostate. The bladder is moth-eaten and ragged and has the appearance of one that is obstructed and trabeculated. This defect may represent the prostate, a tumor—neoplasm of the bladder—or a blood clot but I do not believe it is either. I think it is probably prostate plus trabeculation. Although I am always looking out for pitfalls at these conferences, I shall hazard a

CASE 26091

PRESENTATION OF CASE

A fifty-six-year-old man was admitted to the hospital complaining of painless hematuria.

The patient had enjoyed perfect health until one week before admission when for the first time he passed a large amount of bright-red blood in his urine. Following this he noticed a sharp non-radiating pain in the right flank, which lasted some twenty minutes and disappeared gradually without residual discomfort. He continued to pass blood in decreasing amounts for the next four days. For three days before admission, however, the urine was "dark," but no fresh, bright-red blood was noted. He had experienced no chills, fever, nocturia, frequency, urgency, dysuria or pyuria. He had lost no weight and had noted no other symptoms.

The patient had been in close contact with a brother, who had spent six months of the past year in a local sanatorium because of "weak lungs," and a niece, who had died of tuberculosis eight years before the patient's present illness. The remaining family, marital and past histories were negative.

Physical examination revealed a slender, well-developed man, who lay quietly in bed in no apparent distress. The teeth were carious. Examination of the heart, lungs and abdomen was not remarkable. The genitalia were negative except for the presence of a small, smooth, cystic mass in the globus major of the right epididymis. The rectal examination was negative. The blood pressure was 150 systolic, 80 diastolic.

The temperature, pulse and respirations were normal.

Examination of the blood revealed a red-cell count of 5,300,000 with 177 gm hemoglobin (photoelectric-cell technic), and a white-cell count of 19,000 with 78 per cent polymorphonuclears. The blood smear was negative, the platelets were normal. The urine was cloudy, amber in color and acid, with a specific gravity of 1.016 and a + albumin test. The sediment contained 40 to 150 red blood cells, 5 to 8 white blood cells and 2 epithelial cells per high-power field. The blood Hinton test was negative. The blood sugar and nonprotein nitrogen determinations were normal.

Culture of bladder urine showed a moderate growth of *Staphylococcus aureus* and an abundant growth of nonhemolytic streptococci.

Intravenous pyelograms showed that the kidneys were normal in size, shape and position. There were no visible stones. The intravenous dye appeared promptly and demonstrated normal urinary passages on the left. On the right side there was a sharply defined filling defect occupying the upper major calyx and upper portion of the renal pelvis. The lateral margin of the pelvis in this area showed a slight pressure defect, and there appeared to be slight spreading of the upper and middle calyces. The bladder showed a pressure defect in the region of the prostate. A right retrograde pneumopyelogram confirmed these findings. There was a definite intrapelvic filling defect of the right kidney, which was the same size and shape as that previously demonstrated by the intravenous pyelograms. The margins of this defect were slightly irregular, and it appeared to extend upward along the upper calyx of the kidney. The bladder was not demonstrated.

On the fifth hospital day an operation was performed.

DIFFERENTIAL DIAGNOSIS

DR. J. DELLINGER BARNEY: The causes of hematuria are legion and we cannot go into all of them here. When we speak of painless hematuria we usually mean that there are no particular symptoms associated with it. This patient had right flank pain, and there are many causes, of course, for that. But we have to consider the possibility that this man had a tumor in this kidney, the pain being caused not by the tumor but by the formation and passage of large blood clots. Or he might have had an acute inflammatory disease of the kidney—I refer to carbuncle or multiple cortical abscesses. Or, he might have had a pyelonephritic abscess, or an acute hemorrhagic nephritis, in which, as Dr. Holmes and I recall very well, the findings may very strongly suggest those of a renal tumor. The fact that he had lost weight indicates it was not a long-standing process.

His association with two individuals who apparently had tuberculosis might throw some light on the question, but I do not believe it does in this particular case. With the story we have already heard and contact with these individuals, we have to consider the possibility of tuberculosis of the urinary tract. On the other hand, in my experience, renal tuberculosis does not produce massive hematuria or pain, and there is microscopic hematuria rather than gross.

The fact that the temperature, pulse and respirations were normal indicates there was no acute

systolic, 75 diastolic, and she began to vomit. Examination of the eyegrounds showed beginning choked disks. There were no signs of meningeal irritation at this time. Vomiting persisted for a week, despite the administration of intravenous glucose.

Ten days after the appearance of the puffy eyelids the blood nonprotein nitrogen was 81 mg per 100 cc., the serum protein 4.9 gm., and the cholesterol 191 mg. There was beginning pitting edema of the ankles and in the sacral region. Another lumbar puncture done two days later showed an initial pressure of 350 mm of water and 15 cc. of "ground glass" fluid was withdrawn. The fluid contained 1700 cells per cubic millimeter, 87 per cent of which were polymorphonuclears. The total protein was 46 mg per 100 cc., and the sugar 43 mg.

No organisms were seen in the smear.

At the end of thirty-eight days the temperature again rose to 104.0°F., but no further surgery was attempted. Vomiting persisted, there was some frontal headache, and the general condition did not appear to be very good. Subsequent lumbar punctures showed continued cloudy fluid under increased pressure, there appeared stiffness of the neck, bilateral Kernig signs and a Brudzinski sign, and the optic disks were markedly blurred. The urine showed a trace of albumin with 8 to 10 white blood cells per high-power field and a few casts. The white-cell count of the blood, which had ranged between 19,000 and 25,000, rose to 35,000 and then to 50,000. Cultures of the spinal fluid showed hemolytic streptococci on three occasions, and the spinal fluid sugar dropped to 16 mg per 100 cc. On the forty-first hospital day she had a generalized convulsion, became comatose and exhibited markedly irregular breathing. She died two days later, on the forty-third hospital day.

DIFFERENTIAL DIAGNOSIS

DR. THEODORE H. INGALLS This patient started off with a protracted and fatal illness with an acute otitis media following an upper-respiratory infection. The right drum ruptured spontaneously, was later incised, and continued to drain for two months, making the diagnosis of right mastoiditis presumptive if not certain. It is of merely passing interest that otitis media had occurred two and a half years before entry and that her tonsils and adenoids had been removed long before either infection. Whether "inflammation of the kidneys" a year before entry represented pyelitis, nephritis or simply a lay diagnosis I am unable to say.

She was admitted to the hospital with postaural tenderness, obviously related to mastoiditis on the

right. For the following week, during which she was studied and presumably x-rayed for signs of osteomyelitis, her condition remained substantially the same, with discharge persisting from the ear, a fever of 100.0 to 103.0°F and an elevated white cell count. Then there occurred a change to which I am inclined to attribute considerable significance. The temperature rose to 105.5°F and she vomited several times. Since this occurred before operation, and in fact must have been the main consideration leading to operation the same day, it seems likely that it represented a sudden extension of a septic process in the way of a phlebitis of the lateral sinus. In point of fact a definite phlebitis resulting from a perisinus abscess was found, and a hemolytic streptococcus cultured from the blood stream two days later. I am inclined to believe that the phlebitis dated from the first sharp temperature rise and that streptococci could likewise have been recovered from a blood culture taken at that time. Exactly when the patient picked up the streptococcus is difficult to say. I should suppose that it was in the ear and nasopharynx for some time and that the sudden temperature rise marked its invasion into the blood stream. One cannot help speculating as to whether a massive initial dose of sulfanilamide administered immediately after the temperature rise and prior to operation would have changed the end result—it is obvious that this case antedates the sulfanilamide era.

Three days after mastoidectomy and one day after ligation of the jugular vein, two other changes occurred which are suggestive, although perhaps misleading. A positive Kernig sign and a stiff neck were elicited in the face of a normal lumbar puncture, and "transient severe pain" occurred in the right hip. Since this child had a phlebitis that was feeding bacteria into the blood stream, these symptoms suggest metastases to a joint and to the central nervous system, well-recognized sites of predilection when extension does occur. However, no objective signs were later recorded that suggest involvement of the hip in a septic process, and the transient stiff neck might be related to dural irritation in the neighborhood of the lateral sinus.

From this time on the child maintained a high temperature with signs of continued infection as revealed by the appearance of a discharging ear on the left, although there was a generally favorable reaction to transfusion, with subsidence of the temperature by lysis to a little over 100.0°F.

Choking of the disks, which then occurred, may reflect an expanding intracranial lesion (abscess) or simply be a result of ligating the jugular vein.

Just eighteen days after the hemolytic streptococcus presumably reached the blood stream, and sixteen days after it had been demonstrated there, the patient developed puffy eyelids and gross hematuria. Although I at first considered pyelonephritis as seriously as glomerulonephritis, the clinical picture of the latter disease is so complete and its time relation—sixteen to eighteen days—to streptococcal invasion so characteristic as to make the latter diagnosis practically compulsory. I find a complicating nephritis in this patient particularly interesting in the light of recent work showing that streptococcal toxin endows homologous (and non-antigenic) kidney proteins with antigenic properties. This explains how a patient such as this might develop circulating antibodies against his own kidney tissue and is one theory as to the etiology of glomerulonephritis. The blood non-protein nitrogen was definitely elevated, and the serum protein just below the critical level—consistent with the pitting edema present clinically. These figures may have been and probably were influenced by anabolic and starvation processes, since it seems doubtful that an adequate food intake could have been maintained during this illness. Taken in conjunction with the urinary findings they suggest a mild renal insufficiency, which I do not believe constitutes uremia. The blood pressure was only slightly elevated, whether from the intracranial or renal disease I cannot say.

At the end of thirty-eight days the patient developed a terminal meningitis with spinal rigidity and marked choking of the disks. The temperature and white-blood-cell count rose markedly, the spinal-fluid sugar dropped to 16 mg per 100 cc, and streptococci were cultured on three occasions. I do not know whether this resulted from the extension of a brain abscess into the subarachnoid space—an unusual occurrence—or to direct extension of the septic process in the right mastoid region, which is more likely on the basis of chance.

The facts that some improvement was manifest after transfusion and that the white blood-cell count was maintained between 25,000 and 50,000 terminally again bring one back to speculate whether sulfanilamide administered when the phlebitis developed might not have proved of decisive therapeutic aid.

DR HAROLD L. HIGGINS *Streptococcus haemolyticus* meningitis following a mastoiditis usually occurs by extension extradurally from a perisinus abscess or intrapially from a neighboring metastatic brain abscess. At first the meningeal infection is localized, and the meningitis will frequently subside of itself, if the extrameningeal

pus is drained, unfortunately, it was not the case here.

The usual etiology of hemorrhagic nephritis is an acute hemolytic streptococcus infection fourteen to twenty-one days previously and chilling of the body within twenty-four hours, we have no history of chilling in this case. The occurrence of nephritis while the streptococcal infection is still present leads to a more persistent nephritis and a poorer resistance to the bacteria, we observe this here.

CLINICAL DIAGNOSES

Right otitis media, suppurative, acute, with mastoiditis
Lateral (right) sinus thrombosis
Acute nephritis
Meningitis

DR INGALLS'S DIAGNOSES

Otitis media chronic, right ear, acute, left ear
Osteomyelitis, right mastoid
Perisinus abscess, right lateral sinus
Thrombophlebitis, right lateral sinus
Meningitis, streptococcal
Brain abscess?
Glomerulonephritis

ANATOMIC DIAGNOSES

Acute meningitis, hemolytic streptococcus
Mastoiditis, acute and chronic, right
Otitis media, acute, left
Sinus thrombosis, both lateral sinuses, torcular and posterior portion of superior longitudinal sinus
Nephritis, acute glomerular
Septicemia, hemolytic streptococcus
Hydropéricardium
Ascites, slight

PATHOLOGICAL DISCUSSION

DR. TRACY B. MALLORY Dr Ingalls was quite correct in his surmise that this case antedated the sulfanilamide era. At the present time sulfanilamide would almost certainly have been given a trial and it is quite possible that the outcome would have been different. In fact the most notable difference attributable to chemotherapy in the material which reaches our autopsy table is the marked diminution in the complications of middle ear and mastoid disease.

The autopsy showed a diffuse seropurulent meningitis. Hemolytic streptococci were recovered on culture, and chains of cocci were readily visible microscopically in sections of the meninges. There was no cerebral abscess. Rather extensive granular thrombosis was found involving the pos-

terior half of the superior longitudinal sinus, the torcular and both lateral sinuses extending as far as the jugular foramen on the left side and to the region of the emissary vein on the right. The petrosal and cavernous sinuses were negative. There was still some persisting infection in a few mastoid cells near the posterior portion of the process. The left mastoid was negative, but the left middle ear contained frank pus. The ethmoid and sphenoid cells were negative.

The other important finding was the condition of the kidneys. They were greatly enlarged, weighing 400 gm, as against a cardiac weight of 150

gm. The cortices were something over a centimeter in thickness and appeared very pale, with scattered bright red petechiae.

On microscopical examination no normal glomeruli could be found. There were marked endothelial proliferation, considerable hemorrhage and fibrin deposit, and occasionally slight crescent formation. From the appearance of the kidneys I should guess that there had been a real uremia in the terminal stages. There was a moderate amount of fluid in the pericardium, this was faintly turbid, but there was no fibrin and a septic pericarditis could be excluded.

WHAT IS OSTEOPATHY?

THIS question has been asked on numerous occasions recently in medical literature and the answers have been such that there appears to be a golden opportunity for some medical historian to write in objective fashion an account of the rise of this branch of the healing art. He should not be a historian who presents merely an aggregation of facts, but one who realizes that "it is by solidity of criticism rather by plenitude of erudition that the study of history steadies and straightens and extends the mind," and that "history rescues us from the temporary and the transient and compels us to fasten on abiding issues"

The method of treatment known as osteopathy began with the relief given to one patient and was then applied to others, with what relative success we shall never know for no failures were

reported, yet the true scientist thinks "error treated thoroughly nearly as remunerative as truth, by the discovery of new objections" From those inadequately studied cases, wide inductions were drawn concerning the origin or cause of disease and its treatment. The variations in the scope of the inductions are in part responsible for the variations in the definitions of osteopathy

Osteopathy is a mechanical and kinetic theory of disease, in that impairment of the rate of flow of nerve impulses—later views also included blood and lymph flow—is judged to produce disease. Such impairment occurs most frequently when bony structures are close to nerves, as along the spinal column, specifically at the points of emergence of nerve roots, but may occur in other parts of the body. Dislocations of the vertebrae, minimized for contemplation by the term subluxations, are the chief underlying etiologic factors

In the early enthusiasm, no other cause for disease was recognized or deemed necessary, and no method of treatment except corrective manipulation was applied. Thus, when early legislative recognition was given, it specified that the osteopath should not use drugs, nor should he perform surgical operations. This gives a general definition of osteopathy as a system of treatment: it is a system of corrective manipulation, without the use of drugs and without surgical operations. It is important to keep this fundamental idea in mind, and it is not necessary to ask at this point just what system of corrective manipulation it comprises

Throughout the years there has occurred a significant shift in thought on the part of many osteopathic physicians, with a breaking down of distinctions to the point of utter confusion. This is exemplified by the testimony in a recent court case in Kansas*. In that state there is one board of examiners issuing licenses "to practice medicine and surgery" and another granting those "to practice osteopathy." In the case referred to, the defendant, licensed by the second board, practiced medicine and surgery, which was held by the

*Osteopathy. As taught and practiced in the legally incorporated colleges of osteopathy of good repute. Constructed. Medicolegal Abstracts. Bureau of Legal Medicine and Legislation. J. A. M. 4: 113-447. 1939.

complainant to be a violation of the law. The defendant had received a certificate granting him the right to practice osteopathy in the state of Kansas, as taught and practiced in the legally incorporated colleges of osteopathy of good repute. It was suggested by him that osteopathy had abandoned its fundamental opposition to drug therapy and operative surgery, and now includes the use of these things in its system of healing. Furthermore, it is known that reputable schools of osteopathy include courses in these subjects in their curricula.

The court held that the osteopathic act did not authorize licentiates to use drugs in so far as such drugs are given as remedial aids, nor did it authorize them to practice in the general field of operative surgery with surgical implements, but limited them to manipulative surgery. Therefore the court ousted the defendant from the practice of medicine and surgery.

The significance of this incident from the point of view of the definition of osteopathy is that claims were publicly made by a representative osteopathic physician that osteopathy is what a school of osteopathy teaches and that a licentiate authorized to practice osteopathy is authorized by the Kansas law to practice drug therapy and instrumental surgical therapy, just because reputable schools of osteopathy have enlarged their courses of study to include these subjects. The rejection of this claim by the court is especially welcome because the phrase "as taught in a reputable school" constantly creeps into proposed legislation for branches of the healing art other than osteopathy, and it is often feared with some justification, that the proposed limits for the license might be gradually and quietly extended to cover a much larger field of practice than was claimed at first.

It may be said in conclusion, that regardless of whatever system of corrective manipulative procedures osteopathy may prove to be on investigation it has not changed its essence. If it does, it is no longer osteopathy, it becomes something else. It cannot adopt drug therapy or operative instrumental surgery. In a school of medicine in which someone teaches osteopathy, someone may

also teach drug therapy or instrumental surgery or even science. Of course, if the law permits, a graduate of an osteopathic school may use drugs if he sees fit, but no matter what any physician may do, osteopathy cannot adopt the principle of drug therapy.

The distinction is of no slight importance because efforts are ever in the making to cloud the issue, to misrepresent solidity of criticism as partisan persecution, and always, always, to avoid facing the facts.

CHILD ADOPTION

A RECENT article on adoption by Dr Douglas A. Thom¹ is well worth consideration, and is of particular interest when considered together with a similar paper by Dorothy Thompson² published only a few months previously. One article is fundamentally scientific and appropriately cautious, and the other is distinctly emotional in its appeal, but both arrive at the same basic conclusion.

As stated by Dr Thom, the conclusion is that the problem at the moment is not one of getting the perfect child into the perfect home, but rather the broad, sociologic problem of bringing together the largest number of acceptable children and the largest number of acceptable homes, with the objective of increasing the sum total of the satisfactions to be derived by both adoptive parent and child, and with the minimum amount of risk of creating incompatible relationships."

Adoption is obviously a serious business. With this in mind there is a tendency on the part of certain adoption agencies so to safeguard the interests of both child and prospective parents that the difficulties and delays often seem insuperable. It would appear, indeed, to the casual observer that the requirements for adoption are based on considerably higher standards than would obtain for natural children in decent if not *de luxe* strata of society.

As Dr Thom further says, the problem of bringing together the largest number of acceptable homes and the largest number of acceptable children cannot be satisfactorily settled unless care

ful investigations are carried out by a group of trained investigators who will determine the obvious reasons why an adoptive procedure would not be successful. From such an investigation could be determined the "reasonable liabilities which must be assumed by both adoptive parents and adoptive child, comparable to the liabilities that invariably occur in the natural parent-child relationship."

In determining the risks involved, it must be remembered that the adoptive parents must make many adjustments. The decision for adoption comes as the result of one or more reasons, which may be carefully considered or may be largely emotional. Perhaps usually an excess of the maternal instinct is at work, perhaps the adoption is decided on from a deep-seated sense of duty, perhaps it is used as the last means of saving a marital situation. In any event the motives are apt to be mingled, and the psychological setup is quite different from that which exists in the natural relationship.

As a matter of fact, most adoptions appear to be highly successful arrangements, and it is pertinent for both Dr. Thom and Miss Thompson to raise the query as to why there should not be more of them. Miss Thompson rightly decries the policy, now happily becoming outdated, of sending illegitimate parent and illegitimate child into the world together to share their mutual woe. She shows, unfortunately, a lack of familiarity with some of the real problems associated with the procedure of adoption.

Also of considerable timely interest in this subject, and emphasizing the necessity for careful investigation before adoption, is the recent exposé² of certain baby-selling maternity homes. In these both the unmarried mother and the adopting parents are mulcted until the law occasionally catches up with the racket and forces it at least to change its place of business.

MEDICAL EPONYM

BEARD'S DISEASE

A paper entitled "Neurasthenia or Nervous Exhaustion," which was read by George M. Beard (1839-1883), then lecturer on nervous diseases at the University of New York, before the New York Medical Journal Association, led to the designation of this condition by the name of its author. The article may be found in the *Boston Medical and Surgical Journal* (80:217-221, 1869).

The morbid condition or state expressed by this term has long been recognized, but the special name *neurasthenia* is now, I believe, for the first time presented to the profession.

I have for some time been in the habit of employing the term *neurasthenia* to express the morbid state that is commonly indicated by the indefinite phrase, nervous exhaustion.

The derivation of the term *neurasthenia* is sufficiently obvious. It comes from the Greek, and being literally interpreted signifies want of strength in the nerve.

In regard to the pathology of *neurasthenia* we are compelled, in the absence of definite knowledge, to reason from logical probability.

My own view is that the central nervous system becomes dephosphorized, or, perhaps, loses somewhat of its solid constituents, probably also undergoes slight, undetectable, morbid changes in its chemical structure, and, as a consequence, becomes more or less impoverished in the quantity and quality of its nervous force.

Among the special exciting causes of *neurasthenia* may be mentioned the pressures of bereavement, business and family cares, parturition and abortion, sexual excesses, the abuse of stimulants and narcotics, and civilized starvation, such as is sometimes observed even among the wealthy orders of society, and sudden retirement from business.

MASSACHUSETTS MEDICAL SOCIETY

COMMITTEE TO STUDY PROPOSALS FOR BUDGETING THE COSTS OF MEDICAL CARE

The following have been selected by the president, Dr. Walter G. Phippen, to serve on the Committee to Study Proposals for Budgeting the Costs of Medical Care: Dr. Thomas H. Lanman, of Boston, chairman; Dr. John M. Birnie, of Springfield; Dr. James C. McCann, of Worcester; Dr. Michael A. Tighe, of Lowell; and Dr. Shields Warren, of Boston. The president, Dr. Phippen, and the secretary, Dr. Alexander S. Begg, are members ex officio.

AND GYNECOLOGY*RAYMOND S. TITUS, M.D. *Secretary*
330 Dartmouth Street
BostonPUERPERAL SEPSIS TREATED
WITH SULFANILAMIDE

Mrs. E. O., a twenty-year-old para II, about thirty-six weeks pregnant, entered the hospital because of discomfort on November 22, 1938. Labor had not commenced.

The family history was essentially negative. She had had measles and whooping cough, the tonsils and adenoids were removed at the age of four, she had had a mastoid operation at the age of five. Catamenia began at thirteen, were regular with a twenty-eight-day cycle and lasted three to four days. Her last period had begun on March 9, making the expected date of confinement December 16. The previous pregnancy terminated in a low forceps delivery with a normal convalescence. The present pregnancy had been normal.

On admission the temperature was 100.0°F., and the pulse 114, regular and of good volume. She was not conscious of being ill and did not appear to be ill. The blood pressure was 120 systolic, 80 diastolic. The heart sounds were regular and clear, there were no murmurs. The lungs showed good resonance and were clear throughout. The abdomen was enlarged to a size corresponding to the dates. The fetus was in an ROP position, and the fetal heart rate was 132, the sounds being clear and regular. Rectal examination showed a lightly engaged head and a cervix that was not taken up. The pelvis was of the gynecoid type, slightly contracted. The urine examination was negative. A blood Wassermann test was negative.

On November 23, after a twelve-hour labor, the patient was delivered normally of a female child, weighing 5 pounds, 10 ounces. The placenta separated promptly and was expressed intact. The uterus contracted well. The temperature, however, remained elevated through labor, subsequently rising to 101.2°F., with a slightly elevated pulse. The temperature remained at about 101.0°F., and on the evening of November 24 it rose to 104.0, with a pulse of 124 which was of good quality. The fundus was slightly tender. The lochia was not foul.

Blood examination showed a hemoglobin of 75 per cent, a red-cell count of 4,240,000 and a white cell count of 17,400. The patient was given 40 gr. of sulfanilamide, with an equal amount of sodium bicarbonate, in divided doses on November 24,

the same amount on November 25, and 20 gr. on November 26.

The temperature dropped abruptly to normal the morning of November 25, but rose to 103.4°F. in the evening, then it began a gradual decline, reaching normal on December 1. Because of the marked improvement, the patient received no medication after November 26.

She was discharged from the hospital on December 6, with the uterus in good position and well involuted, the vaults clear and a very slight discharge.

Comment. The marked improvement following the use of sulfanilamide is probably an indication that the infection was caused by a hemolytic streptococcus, although there were no blood or uterine cultures to prove or disprove this statement. This patient undoubtedly had the infection when she started in labor, and whether it came from the uterus or from some other source was not determined.

MEDICAL POSTGRADUATE
EXTENSION COURSES

The following sessions of the Medical Postgraduate Extension Courses have been arranged for the week beginning March 3.

BARKSHIRE

Thursday March 7 at 4:30 p.m. at the Bishop House of Mercy Hospital Pittsfield. Common Problems of Neurology. Indications for lumbar puncture. Instructor T. J. C. von Storch. Harry G. Melton, *Chairman*.

BRISTOL SOUTH (Fall River Section)

Tuesday March 5 at 4:30 p.m., at the Union Hospital Fall River. Gonorrhea in the Female. Instructor Oscar F. Cox, Jr. Howard P. Sawyer, *Chairman*.

FRANKLIN

Thursday March 7 at 8:15 p.m., at the Franklin County Hospital Greenfield. Cardiovascular Disease. Eleven important questions about heart disease and their answers. Instructor Ashton Graybiel. Halbert G. Stetson, *Chairman*.

HAMPSHIRE

Thursday March 7 at 4:00 p.m., at the Academy of Medicine, Professional Building, 20 Maple Street, Springfield and at 8:15 p.m., in the Outpatient Department of the Skinner Clinic Holyoke Hospital Holyoke. Cardiovascular Disease. Eleven important questions about heart disease and their answers. Instructor Samuel A. Levine. George L. Schadt, *Chairman*.

HAMPSHIRE

Thursday March 7 at 4:15 p.m., in the Nurses Home of the Cooley Dickinson Hospital Northampton. Convulsions in Infants and Children. Etiology and treatment. Instructor R. Cannon Eley. Warren P. Cordes, *Chairman*.

A series of selected case histories by members of the section will be published weekly. Comments and questions by subscribers are solicited and will be discussed by members of the section.

MIDDLESEX SOUTH

Tuesday, March 5, at 4 30 p.m., at the Cambridge Hospital, 330 Mt. Auburn Street, Cambridge. Pneumonia Instructor Chester S. Keefer Dudley Merrill, *Chairman*

NORFOLK

Thursday, March 7, at 8 30 p.m., at the Norwood Hospital, Norwood. Complications in Obstetrics, Illustrated by Case Histories Instructor John Rock Hugo B. C. Riemer, *Chairman*

NORFOLK SOUTH

Monday, March 4, at 8 30 p.m., at the Quincy City Hospital, Quincy. Indications for Cesarean Section Instructor M. V. Kappius David L. Belding, *Chairman*

PLYMOUTH

Tuesday, March 5, at 4 00 p.m., in the Nurses' Home of the Brockton Hospital, Brockton. Syphilis in Pregnancy and the Offspring Instructor Rudolph Jacoby Walter H. Pulsifer, *Chairman*

SUFFOLK

Thursday, March 7, at 4 30 p.m., in John Ware Hall, Boston Medical Library, 8 Fenway, Boston. Head and Spine Injuries Instructor Donald Munro Reginald Fitz, *Chairman*

DEATHS

CUSHMAN—ANDREW B. CUSHMAN, M.D., of South Dartmouth, died February 13. He was in his eighty-fifth year.

Born in Freetown, Massachusetts, he attended the University of Vermont and received his degree from the University of Vermont College of Medicine in 1886.

Dr. Cushman was a fellow of the Massachusetts Medical Society and the American Medical Association, and was a member of the New Bedford Medical Society.

A son and a daughter survive him.

KELLEY—JOSEPH H. H. KELLEY, M.D., of Dorchester, died February 18. He was in his sixty-fourth year.

Born in Boston, he graduated from Tufts College and received his degree from Tufts College Medical School in 1898.

Dr. Kelley was a member of the Massachusetts Medical Society and the American Medical Association.

His widow, a daughter and a sister survive him.

MURRAY—GEORGE A. MURRAY, M.D., of South Boston, died January 21. He was in his fifty-sixth year.

Born in Boston, he attended Boston College and received his degree from Harvard Medical School in 1915. For several years before and after the World War he was associated with the Mayo Clinic in Rochester, Minnesota. He was a former member of the Massachusetts Medical Society and the American Medical Association.

His widow, a daughter, a son, a brother and a sister survive him.

PEIRCE—GEORGE A. PEIRCE, M.D., of Enfield, New Hampshire, died February 21. He was in his sixty-sixth year.

Born in Boston, he attended Boston Latin School and received his degree from Harvard Medical School in 1898. Dr. Peirce was formerly the assistant superintendent at the

Massachusetts State Infirmary at Tewksbury, but retired five years ago.

He was a member of the Massachusetts Medical Society, the American Medical Association and the New England Society of Psychiatry.

A son and a daughter survive him.

VICKERY—HERMAN F. VICKERY, M.D., of Brookline, died February 22. He was in his eighty-fifth year.

Born in Rochester, New York, he attended Harvard University and received his degree from the Harvard Medical School in 1882. He studied at the University of Leipzig and also served in the Vienna General Hospital. He began practice in Boston and became an instructor of clinical medicine at the Harvard Medical School. Dr. Vickery was physician to the outpatients at the Massachusetts General Hospital from 1885 to 1898, and visiting physician from 1898 to 1914, when he was appointed to the consulting board.

He was a fellow of the Massachusetts Medical Society and the American Medical Association, and was a member of the Boylston Medical Society and the Association of American Physicians.

His widow, two daughters and a son survive him.

MISCELLANY

MAINE NEWS

NEW LICENSEES

The Board of Registration of Medicine lists the following physicians as licensed through examination, as of November 15, 1939:

Karl V. Anderson, M.D. (Tufts '39), Lewiston.
 Samuel Bachrach, M.D. (Tufts '38), Worcester, Massachusetts.
 Kenneth C. Banting, M.D. (Western Ontario '32), Elnora, New York.
 Henry A. Brann, M.D. (Boston University '39), Augusta.
 Dexter Clough, 2nd, M.D. (Pennsylvania '39), Bangor.
 Paul E. Floyd, M.D. (Harvard '39), Portland.
 Norman Jackson, M.D. (Albany '39), Lewiston.
 John C. Myer, M.D. (Hahnemann '39), Providence, Rhode Island.
 Helen Provost, M.D. (Boston University '35), Augusta.
 William D. Reid, M.D. (Harvard '09), Newton, Massachusetts.

 Byron M. Harman, M.D. (Pennsylvania '17), Verona, New Jersey.
 Milton S. Thompson, M.D. (Harvard '31), Boston.

REMOVAL NOTICES

The following removal notices have been received:

W. H. Kelly, M.D., from Biddeford to Waterboro.

- L. A. Parella M.D., from Lewiston to North Haven Connecticut.
 G. W. R. Bowie, M.D., from Rangeley to New Gloucester.
 R. E. Williams, M.D. from New Gloucester to Freeport.
 E. D. Humphreys, M.D., from Jackman to Pittsfield.

MAINE MEDICAL ASSOCIATION

The following physicians have been recently admitted to membership in the Maine Medical Association

- Gordon N. Johnson, M.D., Portland.
 Philip Gregory M.D., Boothbay Harbor.
 Clarence J. Kenney M.D., Togus.
 Herbert T. Clough, Jr., M.D., Bangor.
 Richard T. Munce, M.D. Bangor.
 Walter L. H. Hall M.D., Old Town.

RHODE ISLAND NEWS

WALTER LEE MUNRO

We think of the late Dr. Walter Lee Munro not only as a great doctor but as a great man—a dynamic and truly unique personality.

Born in Bristol, Rhode Island, in 1857 he came of old Pilgrim stock. Educated in the Bristol schools, he took his A.B. degree at Brown University in 1879 and his M.D. at Harvard University in 1885 and practiced his profession in Providence until the very day of his death. As surgeon to the Rhode Island Hospital and consultant to many other hospitals in Providence and throughout Rhode Island and as a private physician with a large practice among people of all nationalities, creeds and social statuses he served his community well for over fifty years.

Strong but gentle, wise but simple, devoted to his family but sacrificing his personal comfort to the demands of his practice, ever alive to the growth of medical art and a close student of its expanding literature, applying practically what he heard saw or read, treating his patients in and out of hospitals, as people, not subjects, he fulfilled well our ideal of the "perfect doctor." He wrote many creditable medical papers and reports, also many fascinating monographs on lay subjects bearing on the past of his alma mater—Brown University,—the last of these appearing only a month before his death.

A great reader he retained with clear-cut memory what he read, as also the events of his own long and varied career. An athlete and hunter a world-wide traveler a bon vivant, he was, more than all, a friend. Friendship and friendliness were perhaps the outstanding characteristics of this doctor who loved and was loved by the world. He just could not help being friendly and hospitable. Partial deafness as well as blindness were his lot in later years, but he simply would not let them "get him," and carried on to the last.

In his death Dr. Munro leaves with us a fine sense of generous manhood which looked out not in. He was a man, healthy in body mind and spirit, whose passing, young at eighty-two, finds the world better for his having lived.

H. DE W.

NOTE

Dr. Chester S. Keefer, associate professor of medicine, Harvard Medical School and junior visiting physician and director of the Second and Fourth Medical Services, Bos-

ton City Hospital gave the annual Henry Sewall Memorial Lecture of the Medical Society of the City and County of Denver on January 30. The title was "Hemolytic Streptococcus Infections. Their importance in acute and chronic disease."

CORRESPONDENCE

MASSACHUSETTS DENTAL SOCIETY

To the Editor: A most cordial invitation is extended to the members of the Massachusetts Medical Society to attend the evening program of the Massachusetts Dental Society which will be held in the Georgian Room, Hotel Statler Boston, on Wednesday April 24 at eight o'clock. Dr. Eben J. Carey, dean of Marquette University School of Medicine, Milwaukee, Wisconsin will speak on "The Mutual Co-operation in National Health by the Public and the Profession in Medicine and Dentistry." Dr. Walter G. Pluppen, president of the Massachusetts Medical Society will speak on "The Attitude of Organized Medicine in Regard to Socialized Medicine."

WILLIAM H. GRIFFIN, President
 Massachusetts Dental Society

106 Marlborough Street,
 Boston.

REPORTS OF MEETINGS

GREATER BOSTON MEDICAL SOCIETY

A regular meeting of the Greater Boston Medical Society was held at the Beth Israel Hospital on December 5 with Dr. Max Ritvo introducing Dr. Emil Novak, of Baltimore, who spoke on "Gynecologic Endocrinology and Organotherapy." In view of the fact that intelligent organotherapy must follow a fundamental knowledge of the underlying endocrinology the speaker first reviewed the physiology of menstruation. He discussed the production of the estrogens, which persist throughout the cycle, by the ripening follicles and that of progesterone which occurs only in the second half of the cycle, by the corpus luteum.

Dr. Novak then summarized the physiologic effects of the so-called sex hormones. The estrogens, which are much more universally distributed than progesterone, were described as being fundamentally growth hormones with selective activity on the Mullerian system. Thus, they are responsible for an increased blood supply and maturation of the reproductive tract. They also cause the rhythmic contractility of the uterine musculature and proliferative changes in the breast and are instrumental in the development of secondary sexual characteristics. The best examples of this in the human being are the results observed in functioning endocrine tumors before puberty and after the menopause.

Progesterone on the other hand, is a much more specific hormone, which appears to be present only following ovulation. Its effect is produced only on endometrium already primed by estrogen and results in the secretory phase, with its increased glycogen content. Indeed, the appearance of the endometrium after the combined action of the two hormones so closely resembles the early decidual reaction of pregnancy that the two conditions are differentiated only with difficulty on that basis alone. It was pointed out that since the corpus luteum is in reality merely a metamorphosed follicle, the close similarity in chemical structure of the two hormones is not surpris-

ing Further work has served to divide the nebulous "internal secretion of the ovary" into a group of crystalline compounds

Dr Novak then discussed the non pelvic origins of hormones that affect the reproductive organs. He cited the well known experiments, since the first description of Frohlich's syndrome, which have resulted in the hypothesis that the pituitary gland, through its gonadotropic hormones, probably has a governing role. The evidence for two separate tropic substances is now almost incontrovertible, one (FSH) stimulates the maturation of the follicle and the other (LSH) causes the luteinization of the ripe follicle. Unfortunately there has been no isolation of either substance of proved purity or measurable activity. Recent experiments, however, seem to indicate that the gonadotropic substance isolated from the urine of pregnant mares is efficacious as a follicle stimulating hormone.

Another source of physiologically active sex hormones is the urine of pregnant women, which contains anterior-pituitary-like substances (APL) rather than true overflow pituitary hormones. There are also two distinct endocrines here, sometimes called the prolans. Their origin is now proved by tissue culture, as well as by physiological experiments, to be in the trophoblastic shell of the implanted ovum. Any living, active trophoblast with access to the maternal circulation is capable of producing these substances, which Dr Novak suggested should be called chorionic hormones. These prerequisites for their presence in the maternal blood explain why a positive Aschheim Zondek test is usually found in cases with chorionepithelioma and why a negative test may be encountered in an inactive tubal pregnancy.

The final substance employed in female organotherapy is testosterone propionate, one of the androgenic principles which is closely allied structurally to progesterone and the adrenal hormone, desoxycorticosterone. Although the results are still controversial, the effect of testosterone on the endometrium appears to be one of antagonism to estrogen during the first half of the menstrual cycle and of supplementation to progesterone after ovulation.

Dr Novak then proceeded to a discussion of organotherapy in various female endocrinopathies. The first consideration was that of functional uterine bleeding, which may be such a plague especially at puberty and the menopause. Dilatation and curettage may often check the condition only temporarily, if at all, and patients have been known to go on to exsanguination during such episodes. The cause of the disorder may be primarily one of ovarian dysfunction, due either to the persistence of an unruptured follicle or to the continued development of more than one follicle. The speaker warned that, in the evaluation of any therapy, this disorder is notorious for its spontaneous remissions and self-limited course. The treatment should consider the phase of the reproductive life of the patient and the desire for children. A complete physical examination and a diagnostic dilatation and curettage should always be carried out in order to rule out organic disease as a cause of the metrorrhagia. At the time of the menopause, the use of radium rather than surgery was recommended unless there was some other indication for laparotomy.

In regard to the hormones, the results in no instance proved conclusively that they were of benefit, but Dr Novak said that sterilization procedures were too radical in the child-bearing age without a previous attempt at conservative treatment. The various progesterone and prolan products should probably be given only at the time of bleeding, after determining that it is not a true menstrual period. Occasionally there is marked alleviation of

symptoms and occasionally none, while usually there is moderate relief. Testosterone should probably be administered throughout the cycle after sufficient control periods have been observed. This more frequently gives favorable results, but in large doses may occasionally result in slight and transient masculinization. Its mechanism was postulated as an inhibition of estrogen through the anterior pituitary gland.

In the treatment of metrorrhagia at puberty, Dr Novak emphasized the desirability of advising the mother of the protracted period of adjustment which often occurs before a spontaneous termination of the condition occurs. If organotherapy fails, repeated dilatations and curettage should be attempted, with radium implantation being reserved only as a last resort. The speaker made the pertinent suggestion that in any case necessitating transfusion, a donor should be selected, if possible, who is three to four months pregnant.

In opening the discussion, Dr Joseph C. Aub emphasized the importance of an evaluation of the substrate in any undertaking with organotherapy. This is particularly important in those transition periods of puberty and the menopause. In the former phase there is a crescendo development of the gonadal hormones and the substrate is more susceptible to substitution therapy than in the menopausal patient with her decadent hormonal system. Dr Aub asked Dr Novak's views on dysmenorrhea.

The discussion was continued by Dr Max Davis, who warned of the potential dangers in these therapeutic agents and cited cases of masculinization following the use of even small doses of testosterone. He asked Dr Novak whether he considered it possible to find the secretory phase in an endometrial biopsy from a patient who had not ovulated.

Dr Samuel L. Gargill was of the opinion that most patients with metropathia hemorrhagica are subnormal physically and nutritionally, particularly in respect to vitamins. In those who have a large leathery thyroid gland similar to that of thyroiditis, and who have a low basal metabolic rate, it has been found beneficial to use thyroid therapy.

Dr Novak closed the meeting with a discussion of the problems presented by these men. He was entirely in accord with Dr Aub in regard to the importance of the substrate in causing variable results in organotherapy. In regard to dysmenorrhea, the speaker said that, in certain cases resulting from hypercontractility of the uterus, progesterone might prove helpful through its antagonistic effect on estrogen. This was suggested by its beneficial effects in certain instances of threatened and habitual abortion. He added that there are a certain number of young asthenic girls under the spell of a doting mother whose threshold can be sufficiently elevated by physical and psychical development. The small residue of healthy bodies and minds in whom intelligent organotherapy has failed are the only patients whom Dr Novak considers worthy of presacral ganglionectomy. Exhaustive attempts at conservative treatment in such cases should include all the antiestrogenic hormones—progesterone, testosterone and the various anterior pituitary like substances.

In answer to Dr Davis, the speaker expressed the opinion that the secretory endometrium follows only ovulation, despite suggestive work of Hisaw which showed prosecretory granules in castrated monkeys treated with estrin. He said that the results of Hamlin, who found pregnandiol at periods other than those following ovulation, were probably due to faulty technique.

Dr Novak stated that postmenopausal endometrial hyperplasia could be explained on the persistence of some

estrogenic function following the cessation of external agents. The other hypotheses question the possibility of metabolizing sterols, and more recently point toward the adrenal cortex as the possible site of stimulation in such states.

HARVARD MEDICAL SOCIETY

A regular meeting of the Harvard Medical Society was held at the Peter Bent Brigham Hospital on December 12, 1939.

The first case was that of a forty-nine-year-old Viennese diamond setter who had entered the hospital four months previously with a history of increasing nausea, vomiting and exhaustion appearing in that order over a period of eighteen months. Physical examination revealed an emaciated man with pigmentation of the skin of the exposed surfaces in the axillae and of the genitalia and of the mucous membranes. The blood pressure was 100 systolic, 60 diastolic. A tentative diagnosis of carcinoma of the stomach, with a question of Addison's disease, was made. During his stay in the hospital he collapsed during an x-ray examination, when his blood pressure was found to have a systolic value of 70. Recovery followed the intravenous administration of sodium chloride solution. The serum chloride content ranged from 585 to less than 580 mg. per 100 cc. Urine and sputum specimens each showed acid-fast bacilli only once and then on the same day. X-ray examination of the chest showed no evidence of pulmonary tuberculosis or of calcified lymph nodes in the abdomen. A sodium chloride deprivation test resulted in acute illness, and relief was afforded by the administration of that substance. A diagnosis of Addison's disease was made, and the patient was put on a regimen of the standard high-salt, low-potassium diet with an additional 10 gm. of sodium chloride daily. Daily intramuscular injections of 10 and later 5 mg. of desoxycorticosterone acetate were given while the patient was in the hospital. He was discharged greatly improved at the end of three months, and was told to return about every three days for injections. The present return to the hospital was for the implantation of desoxycorticosterone pellets, computed to yield a daily dose of 1 or 2 mg., which had been determined as the patient's approximate maintenance requirement. There has been a moderate decrease of the general pigmentation but areas of increased pigment at the site of the intramuscular injections were noted.

Dr. Soma Weiss, in discussing the case, stated that the latter phenomenon was undoubtedly due to the increased transport of melanin to the hyperemic area caused by the trauma attendant on the injections. He called attention to the unusually low urinary androgen levels persistently found in this patient, who also complained of decreased libido. The question was raised as to the possibility of elevating the level and improving the associated symptoms with the specific substitution therapy employed. In reply to Dr. William C. Quimby's query as to whether the patient was considered to have tuberculosis, Dr. Weiss stated that it is now questionable whether the chronic destruction observed in the adrenal glands of these patients is actually tuberculous in nature. True tubercles, he said, are not found in this condition. Dr. Joseph C. Aub, in elucidating the problem of the urinary androgen secretion, stated that it was becoming generally accepted that the source of these substances is undoubtedly the adrenal gland and that an inhibition of libido is common.

The second case was that of a seventy-two-year-old man who had had for the past year a dull aching epigastric pain occasionally radiating to the shoulder blades, unassociated with meals, usually occurring during the night, and

relieved to some extent by alkalies and vomiting. Lately the pain had increased in severity and there had been occasional coffee grounds vomitus. There was moderate exertional dyspnea, and minimal ankle edema. Six months prior to entry an x-ray examination showed a questionable ulcer. On admission the blood pressure was 180 systolic, 110 diastolic; there were crackling basal rales and a slightly tender epigastrium. When the patient was unable to take a Sippy diet due to persistent vomiting, Wangensteen drainage was instituted but the patient appeared to be going downhill. The stools were strongly positive for occult blood and the red-cell count fell from 3,400,000 to 2,200,000. Surgery was not considered because of the rales, a fever of 101 F and the x-ray findings of an early bronchopneumonia. After several blood transfusions and the administration of a considerable quantity of parenteral nutrition and electrolytes, the patient improved and was able to tolerate a fourth week Sippy diet. The serum protein under the above therapy increased from 4.2 to 5.4 gm. per 100 cc., and a laparotomy was performed. At operation there was a small benign ulcer of the duodenum with marked spasm and a posterior gastroenterostomy was performed.

Dr. Elliott C. Cutler discussed the problems entailed in this case. In an elderly person one is too prone to consider all such lesions malignant rather than benign, but on the whole it is a healthy attitude if one does not balk at operation when there is some indication for it. He emphasized the improvement in preoperative management brought about in recent years, which proved so beneficial in this patient. The importance of the maintenance of the electrolyte balance in cases with vomiting and gastric drainage and of the serum protein level in those with starvation were stressed.

The speaker of the evening, Professor A. Baird Hastings, was introduced by Dr. Weiss. His subject was "Tissue Electrolytes." Dr. Hastings stated that the introduction of new techniques of study and an improved interpretation of results had merely served to bring closer together the observed values and those expected from an application of the Gibbs-Donnan and other physicochemical laws to the electrolytes of body fluids. These laws do not describe the behavior of tissue electrolytes, however. It was pointed out that analytical data were difficult to obtain for there are several kinds of tissue and cells cannot be maintained for long in the absence of their natural environment.

As a result of experiments it has been shown that the tissues and fluids of the body may be classified as systems of different permeabilities. A membrane permeable to anions and cations, but not protein—the capillary wall—could not obtain in tissues without a progressively increasing intracellular pressure, which is not true except in unusual cases and after death. Blood cells are permeable only to anions of small dimension and to water. Tissues in general are normally impermeable both to anions and cations and permeable only to water and un-ionized molecules.

One of the important findings of Dr. Hastings and his co-workers was the striking resemblance in ionic content of tendon to plasma rather than to muscle. In fact the extracellular phase of tissue was found to be much more like that of diluted connective tissue than of an ultrafiltrate.

Studies on experimental edema with an isotonic solution showed the extracellular swelling to be much greater in an alkaline than in an acid or normal medium. There was also some swelling of the cells in an acid or alkaline medium while dehydration occurred largely in the cellular phase.

HOUSE OFFICERS ASSOCIATION, BOSTON CITY HOSPITAL

At a regular meeting of the House Officers Association of the Boston City Hospital in the Cheever Amphitheater on December 13, 1939, Dr Richard B Cattell spoke on "Malignancy of the Large Bowel"

In introduction Dr Cattell alluded to the great improvement which has taken place in the surgical treatment of these conditions and attributed this largely to a better evaluation of the patients and an improvement in the pre-operative management of the cases. He stated that refinements in technic have been less important.

A tabulation of the Lahey Clinic cases of cancer of the large bowel revealed that about 60 per cent of the lesions occurred in the rectum and 40 per cent in various parts of the colon. Only 39 per cent of lesions in the latter location occurred in men, whereas the incidence in the rectum was 56 per cent. The sex incidence in the entire group, therefore, was about equal when due account was taken of the predominance of rectal lesions. In regard to age distribution, it was noted that the percentage of cases occurring in old age—sixty to seventy-nine—was larger in the colonic than in the rectal group. On the other hand, 16 per cent of the large bowel cancers occurred in those under thirty-nine years of age. Rectal lesions were most frequent from forty to sixty years.

Dr Cattell then briefly discussed methods of diagnosis. An illustration of the inadequacy of most such procedures is the fact that 30 per cent of patients with cancer of the large bowel have hemorrhoids and 15 per cent of all patients have had operative treatment of this condition within six months of the time of examination. The speaker stated that the protean and non-specific character of the symptoms usually prevents an accurate diagnosis by the history alone, but should always serve to arouse suspicion and lead to a thorough examination. In regard to the physical findings, Dr Cattell stated that 50 per cent of colonic carcinomas present palpable, abdominal masses, while 54 per cent of the rectal lesions are within reach of the examining finger in a properly conducted examination. The lithotomy position, even in men, was considered the optimum one.

Proctoscopic examination should be carried out in any suspicious case. An adequate preparation is especially desirable when there are polyps, which Dr Cattell stated occur in almost 3 per cent of the patients. A biopsy may be taken but a negative report by the pathologist should not be given preference over the entire clinical picture, for the superficial portions of malignant adenomas frequently fail to show evidences of cancer. Such endoscopic studies, in addition to a careful physical examination, enable one to make a diagnosis in 75 per cent of the cancerous lesions of the sigmoid and rectum.

Barium and double-contrast enemas should be employed in all suspected cases before ruling out cancer. A certain number must be subjected to laparotomy in the face of negative evidence in all these tests, purely because of a suggestive history. Although 50 per cent of these explorations will be negative, 1 per cent of all cancerous lesions of the large bowel cannot be demonstrated by any diagnostic procedure except exploratory laparotomy.

Dr Cattell enumerated the early symptoms suggestive of large-bowel cancer. Rectal lesions are prone to have bleeding, discomfort due to tenesmus, and a change of bowel habits, whereas colonic lesions present a change of bowel habits, anemia, and blood and mucus in the stools. Abdominal cramps are present in only 7 per cent of the rectal and sigmoidal carcinomas as compared with 80 per cent of those of the colon. The incidence of abnormal

stools decreases from 86 per cent in the lower lesions to 46 per cent in the left colon to 9 per cent in the right colon.

Before discussing the methods and results of treatment the speaker alluded to the rapid strides made in recent years in the number of so-called operable cases. Whereas only 48 per cent of those seen between 1922 and 1924 were considered operable, the percentage for the past two years has risen to 89 per cent of all diagnosed cases of large bowel cancer. These cases were no more favorable than formerly, for this is one group of neoplasms whose delay in treatment still continues. Approximately 10 per cent had liver metastases, many of which, however, were not massive. An additional number have their lives prolonged and the majority have their symptoms alleviated to varying degrees. This lack of selection has naturally decreased the percentage of favorable results and cure, but the presence of a few five-year "cures" in ostensibly inoperable patients has made the procedure definitely worthwhile.

During this same ten-year period when the operability has increased almost 100 per cent, the operative mortality has dropped from 36 per cent to 10 per cent for all types of operations. About 6 to 7 per cent of the patients require some type of enterostomy for obstruction, and a cecostomy is usually employed. The operations of choice in the colonic region are a modified Mikulicz procedure, with no intraperitoneal anastomoses, or a two-stage anastomosis and resection. Procedures carried out for rectal and rectosigmoid cancer are more flexible and vary with the case. Abdominoperineal resections in one or two stages are the commonest, with the latter type having been perfected and used extensively. Other types of operations in this region are loop colostomy and perineal resection, and abdominal resection with a permanent colostomy. The gross salvage in carcinoma of the rectum has been 54 per cent and of the colon 44 per cent for all resected cases.

Dr Cattell also discussed the difficult problem of polyps, with particular reference to the reputedly precancerous, congenital, adenomatous polyps. Single polyps were considered best treated by fulguration through the sigmoidoscope or by sigmoidotomy or colotomy if beyond reach. In the congenital form, all lesions in the rectum are best fulgurated, and an adequate colectomy and ileosigmoidostomy should follow.

Dr E. E. O'Neil stated that he preferred a primary aseptic anastomosis on right-sided colonic lesions rather than a Mikulicz procedure, on the basis that the former was at least as safe and was better economically for the patient. Dr Cattell stated that at the Lahey Clinic the Mikulicz type of operation proved to be the safest procedure, and concluded with the statement that any proved procedure familiar to the individual surgeon may give essentially the same percentage of favorable results.

NOTICES

PETER BENT BRIGHAM HOSPITAL

A research conference of the medical staff of the Peter Bent Brigham Hospital will be held in the amphitheater of the hospital on Tuesday, March 5, at 5 00 p.m. Tea will be served at 4 30 p.m.

PROGRAM

Blood and Urine Iodine in Diabetes Insipidus Dr. H. H. Blotner and H. J. Perkins
Further Observations on Dynamics of Circulation in Patent Ductus Arteriosus Dr. E. C. Eppinger
All interested persons are cordially invited to attend.

JOSEPH H. PRATT DIAGNOSTIC HOSPITAL

Bennet Street, Boston
Lecture Hall, 9-10 a.m.

MEDICAL CONFERENCES

- Friday March 1—Rational Use of Chemotherapy Dr C. A. Janeway
Saturday March 2—Hospital case presentation. Dr S J Thannhauser
Tuesday March 5—Diagnosis and Treatment of Certain Hip Conditions. Dr J D Adams.
Wednesday March 6—Hospital case presentation. Dr Thannhauser
Thursday, March 7—The Phenomena of Taste and Smell. Dr Alexandra Adler
Friday March 8—Indications for Surgery in the Treatment of Peptic Ulcer Dr A. W. Allen.
Saturday, March 9—Hospital case presentation. Dr Thannhauser
Tuesday March 12—Review of Recent Cancer Literature. Dr W. M. Shedden.
Wednesday March 13—Hospital case presentation Dr Thannhauser
Thursday March 14—The Relation of Cancer of the Stomach to Pernicious Anemia. Dr Thomas Fujiwara
Friday March 15—Endocrinology Dr Fuller Albright
Saturday March 16—Hospital case presentation. Dr Thannhauser
Tuesday March 19—Clinicopathological conference Dr D. S. King.
Wednesday March 20—Hospital case presentation. Dr Thannhauser
Thursday March 21—Control of Gonococcal Infection. Dr O. F. Cox.
Friday March 22—Psychotherapy Dr Donald McPherson.
Saturday March 23—Hospital case presentation Dr Thannhauser
Tuesday March 26—X-ray demonstration. Dr Alice Eisinger
Wednesday March 27—Hospital case presentation. Dr Thannhauser
Thursday March 28—The medical, social and preventive aspects of a selected case. Preceptors and medical students.
Friday March 29—Some Observations on Pituitary Adenomas. Dr M. C. Sosman.
Saturday March 30—Hospital case presentation Dr Thannhauser

BOSTON LYING-IN HOSPITAL

The next meeting of the Journal Club will be held on Tuesday March 12, in the lecture hall of the Boston Lying-in Hospital at 8 15 p.m. Dr Douglas P. Murphy of the School of Medicine of the University of Pennsylvania, will present his work on topographic recordings of uterine motility

CARNEY HOSPITAL

The monthly meeting of the John T. Bottomley Society will be held at the Out Patient Department of Carney Hospital on Tuesday, March 5 at 11.30 a.m. Dr Benjamin Risenman will speak on "Vertigo."

Physicians and students are cordially invited to attend.

PETER BENT BRIGHAM HOSPITAL

A joint medical and surgical clinic at the Peter Bent Brigham Hospital will be held on Wednesday March 6 from 2-00 to 4 00 p.m. Drs. Robert Zollinger and E. S. Emery will speak on "Indigestion."

GREATER BOSTON MEDICAL SOCIETY

A meeting of the Greater Boston Medical Society will be held in the auditorium of the Beth Israel Hospital on Tuesday evening March 5 at 8 15

Dr William B. Castle will speak on "The Blood Dyscrasias. An aspect of general medicine." A discussion and question period will follow

ST ELIZABETH'S HOSPITAL

The annual meeting of the Carney and St. Elizabeth's Hospital staffs will be held at St. Elizabeth's Hospital on March 7 at 12 o'clock noon. The meeting will be conducted by the staff of the Carney Hospital. The following papers will be presented

Sulfanilamide Treatment of Appendiceal Peritonitis. Dr John J. Todd.

Menopausal Bleeding. A review of 100 cases. Dr Edmund L. Carey

Simple Methods of Treatment in Fracture of Surgical Neck of Humerus. Dr John L. Doherty

Responsibility of the Urologist in Hypertension. Dr Charles J. E. Kickham.

UNITED STATES MARINE HOSPITAL

A staff meeting of the United States Marine Hospital Chelsea, will be held at "The Hut," on Friday afternoon, March 8 at 4 00. Dr Sylvester B. Kelley will talk his subject being "Injuries to the Urinary Tract."

NEW ENGLAND HOSPITAL FOR WOMEN AND CHILDREN

The monthly clinical conference and meeting of the staff of the New England Hospital for Women and Children will be held at the nurses' residence on Thursday March 7 at 7 15 p.m. Drs. Clem McKoon and Richard Wadsworth will present a case of Simmonds' disease.

CONSULTATION CLINICS FOR CRIPPLED CHILDREN IN MASSACHUSETTS UNDER THE PROVISIONS OF THE SOCIAL SECURITY ACT

| CLINIC | DATE | ORTHOPEDIC CONSULTANT |
|-------------|----------|-----------------------|
| Lowell | March 1 | Albert H. Brewster |
| Salem | March 4 | Harold C. Bean |
| Haverhill | March 6 | William T. Green |
| Gardner | March 12 | Mark H. Rogers |
| Brockton | March 14 | George W. Van Gorder |
| Worcester | March 15 | John W. O'Meara |
| Pittsfield | March 18 | Francis A. Slowick |
| Northampton | March 20 | Garry deN. Hough, Jr |
| Fall River | March 25 | Eugene A. McCarthy |
| Hyannis | March 26 | Paul L. Norton |

AMERICAN BOARD OF INTERNAL MEDICINE, INC.

The American Board of Internal Medicine will conduct oral examinations just previous to the meeting of the American College of Physicians in Cleveland and just in advance of the meeting of the American Medical Association.

ciation in New York City Applicants who have successfully passed the written examination and plan to take the oral examination in 1940 should advise the office of the secretary at least six weeks in advance of the date of the examination they desire to take.

The next written examination for 1940 will be given on October 21 Applications for this examination must be filed in the secretary's office by September 1 Application forms may be obtained from Dr William S Middleton, secretary treasurer, 1301 University Avenue, Madison, Wisconsin

SOCIETY MEETINGS AND CONFERENCES

CALENDAR OF BOSTON DISTRICT FOR THE WEEK BEGINNING SUNDAY, MARCH 3

SUNDAY MARCH 3

- 4 p.m. Backache Dr Frank R Ober Free public lecture. Harvard Medical School amphitheater of Building D
- 4 p.m. Surgical Diseases of Bone. Dr John D Adams Illustrated public health lecture Faulkner Hospital auditorium

MONDAY MARCH 4

- 5 p.m. The Hypothalamus and the Sympathetic Nervous System Dr S Walter Ranson Edward K Dunham lecture. Harvard Medical School amphitheater Building C

TUESDAY MARCH 5

- *9-10 a.m. Diagnosis and Treatment of Certain Hip Conditions Dr John D Adams Joseph H Pratt Diagnostic Hospital
- *11 30 a.m. Vertigo Dr Benjamin Riseman John T Bottomley Society Out Patient Department Carney Hospital
- *5 p.m. Research conference of the medical staff of the Peter Bent Brigham Hospital
- 8 15 p.m. The Blood Dyscrasias An aspect of general medicine Dr William B Castle. Greater Boston Medical Society Beth Israel Hospital auditorium

WEDNESDAY MARCH 6

- *9-10 a.m. Hospital case presentation Dr S J Thannhauser Joseph H Pratt Diagnostic Hospital
- *2-4 p.m. Indigestion Drs Robert Zollinger and E. S Emery Peter Bent Brigham Hospital.
- 5 p.m. Hypothalamohypophyseal Relationships Dr S Walter Ranson Edward K Dunham lecture. Harvard Medical School amphitheater Building C

THURSDAY MARCH 7

- *9-10 a.m. The Phenomena of Taste and Smell Dr Alexandra Adler Joseph H Pratt Diagnostic Hospital
- 12 m Annual meeting of the Carney and St Elizabeth's Hospital staffs St Elizabeth's Hospital
- *5 p.m. Clinicopathological conference Faulkner Hospital
- 7 15 p.m. Clinical conference and meeting of the staff of the New England Hospital for Women and Children

FRIDAY MARCH 8

- *9-10 a.m. Indications for Surgery in the Treatment of Peptic Ulcer Dr A W Allen Joseph H Pratt Diagnostic Hospital
- 5 p.m. The Hypothalamus and Behavior Dr S Walter Ranson Edward K Dunham lecture Harvard Medical School amphitheater Building C

SATURDAY MARCH 9

- *9-10 a.m. Hospital case presentation Dr Thannhauser Joseph H Pratt Diagnostic Hospital

*Open to the medical profession

MARCH 1—Staff meeting United States Marine Hospital Page 331 issue of February 22

MARCH 1-30—Joseph H Pratt Diagnostic Hospital Page 369

MARCH 2 JUNE 8 and 10—American Board of Ophthalmology Page 719 issue of November 2

MARCH 3—Free public lecture. Quincy City Hospital Page 77 issue of January 11

MARCH 7-9—New England Hospital Association Hotel Statler Boston

MARCH 8—Staff meeting United States Marine Hospital Page 369

BOOK REVIEWS

- Asthma.* Frank Coke. With the collaboration of Harry Coke. Second edition. 266 pp. Baltimore The Williams & Wilkins Co. 1939 \$4.00

Thus, the second edition of Dr Coke's book, is interesting chiefly because it accentuates the difference in the treatment of bronchial asthma in England and in the United States. It might be suspected that the allergic problems were inherently dissimilar but, except for the absence of ragweed, they are essentially the same. For the first portions of the book much praise is due. The etiology and the signs and symptoms of asthma are clearly and concisely described. Except for the importance given to the sedimentation rate, his examination of cases follows the general rule. In treatment, however Dr Coke advocates methods which many American allergists would find difficult to accept.

In discussing the treatment of inhalant sensitivity he states (page 199) "At the end of a week of daily injections, he [the patient] should be symptom free and remain so during the remainder of the treatment although it is never possible to give any guarantee of this." In this country such gratifying immediate and complete success is the exception rather than the rule.

Regarding the use of morphine in asthma, there has in the past been some controversy the majority of the workers, however from Salter in 1880 to Henderson and Rice in 1939 have been against its use. Morphine slows the respiratory rate, reduces tidal volume and makes the reflexes affecting respirations more pronounced, probably reducing the sensitivity of the respiratory cells to carbon dioxide. Dr Coke states "I think it is important to give enough morphine when it is used and should suggest one-third of a grain, but morphine sulphate, 1/4 gr., of atropine sulphate, 1/150 gr., is usually sufficient to break the attack." Undoubtedly this treatment will break an attack, but euthanasia when practiced should be practiced unwittingly and not unwittingly by the attendant physician who only too often explains, post mortem that the at-

tack was so severe that not even morphine would control it. In skillful hands in small doses for rare patients, morphine may be useful but it is not a drug to use indiscriminately in the dosage suggested.

Dr Coke also advocates the Danysz vaccine for non-specific treatment. This vaccine, made of "all the organisms found growing in the intestine," is used, apparently with great success, for all types of asthma and also for hay fever due to pollen but not treated with specific pollen extract. In England a specific vaccine made of *Enterococcus faecalis* has been used by Freeman and by Fleming for the treatment of certain types of intrinsic asthma and in this country vaccines of bacteria from the upper respiratory tract have been used by Brown in conjunction with pollen for non-specific treatment in hay fever but the reviewer is of the opinion that almost all allergists are agreed that such non-specific vaccines are indifferent in effect and variable in result. Dr Coke also recommends, but less strongly the use of autobemotherapy and peptone by mouth and by injection—two methods generally considered of little value.

The use of helium by inhalation that of epinephrine in oil by subcutaneous injection and that of aminophyllin and sucrose intravenously are not mentioned. The methods given however safe and successful in the author's hands, are not universally accepted and may if used unskillfully be dangerous.

- A Handbook on Diabetes Mellitus and Its Modern Treatment* J P Bose. Third edition. 272 pp. Calcutta Thacker Spink & Co., Ltd., 1939 Rs. 7-8

This text, intended for the general practitioner and medical student and based on the author's practice in India, includes, in its third edition, a section on blood lipoids, with particular reference to the relation of cholesterol to arteriosclerosis and a chapter on protamine zinc insulin.

Of special interest is the inclusion of data concerning the chemical nature of the Indian dietary the author states "What gout is to the nobility of England, diabetes is to the aristocracy of India." He regards chronic dietary excesses combined with indolent habits as mainly responsible for both. Among 2000 patients 68.2 per cent were Hindus and only 14.6 per cent Mohammedans, the latter figure being slightly less than that for the incidence of Europeans of his series. These differences he regards as artificial since Mohammedan women are so seldom examined medically. However in India as elsewhere, the mortality rate is increasing and the rise between 1929 and 1934 was much greater among the Mohammedans than among any other group. Thus, in the city of Calcutta the diabetic mortality rate was 5.2 per 1000 in 1929 and 20.7 in 1934.

In treatment, the author's usual practice is to put the patient on one of three diets according to racial customs, containing 100 gm. of carbohydrate, 80 gm. of protein and 100 gm. of fat. After a week on such a limited diet, the tolerance is determined and, if necessary insulin given. Then the diet is raised to 30 calories or more per kilogram.

- Diseases of the Foot* Emil D W Hauser 472 pp. Philadelphia and London W B Saunders Co. 1939 \$6.00.

This book is a praiseworthy piece of bookmaking it is profusely illustrated several of the cuts being in color.

The author has devised, and describes, certain appliances and methods of shoe alteration with which his name is associated. He advances certain theories which are not always consonant with common orthopedic practice, mini-

mizing, for example, the value of special exercises for developing and properly balancing the muscles which control the position of the foot in weight bearing—a defeatist attitude which perhaps is not warranted. He places chief reliance on controlling the position of the foot by felt pads and shoe alterations, advising patients to work out their own salvation in locomotion.

Several chapters merit special commendation. In Chapter 3, proper emphasis is given to the fact that the foot is not an isolated organ of locomotion but intimately coordinated with, and influenced by, the mechanics of the body as a whole, the foot in its turn exerts an influence on these same mechanisms. Chapter 4, dealing with the hygiene and general care of the feet, is excellent, as are also Chapter 13 on fractures of the foot and ankle and Chapter 26 on the care of the feet during pregnancy and following prolonged illness. Chapters 27, 28, 29 and 30 on the special technics, including local anesthesia, methods of manipulation and special appliances, are clearly written and will be found to be very useful.

The essential etiology of many foot ills is said to be "functional decompensation", this may be true, but the proof is not always so clear as the reader might wish. In advocating certain operative methods, it seems as though the debt we owe to such outstanding pioneers as Michael Hoke and H. Winnett Orr should be acknowledged.

The book is an attempt to cover all ills of the human foot from an embryological, anatomical, physiological and etiologic background, and the author—a busy and successful practitioner—describes the treatment that he has found most efficient, an approach to the subject which is certainly practical. The task which he set himself was a hard one, he has evidently labored zealously to fulfil it, but has been taken rather far afield.

Mental Health Publication of the American Association for the Advancement of Science, No. 9 Edited by Forest R. Moulton and Paul O. Komora. 470 pp. Lancaster, Pennsylvania: The Science Press, 1939. \$3.50.

This series of papers on psychiatry and its contributions to medicine and to social welfare is extremely valuable. In a sense the audience, which consisted entirely of guests invited by a crucial committee, must be given a large part of the credit for the careful preparation of the summaries which were presented. Propaganda is practically absent. There are only a few instances where pure hope dominates a paper. Almost every contributor presents evidence which indicates an opportunity for better care of mental disease and better use of community resources for the study of mental health in general. The reviewer believes that this volume contains the best summary of psychiatry in relation to the community which is available. Obviously it is not to be used as a textbook, and equally obviously it is not likely to appeal to those who are not already interested.

Diseases of the Skin Richard L. Sutton and Richard L. Sutton, Jr. Tenth edition. 1549 pp. St. Louis: C. V. Mosby Co., 1939. \$15.00.

This edition of an increasingly popular textbook in dermatology is rapidly approaching the status of a single volumed encyclopedia. Not only are all the common diseases of the skin very thoroughly described from every angle, but even the rare dermatoses are adequately considered. Many of the special chapters are so complete that they are practically monographs on their particular subjects. For example, the chapter on diseases due to

fungi, which contains a small table of the characteristics of fungi for laboratory identification by Lewis and Hopper and which consists of 144 pages of material descriptive of fungous infections, is in itself almost worth the price of the entire book. The chapter on syphilis, which consists of about 100 pages and which contains a concise and succinct subchapter on the serodiagnosis of syphilis by Rein, is complete from every standpoint. The chapter dealing with the various diseases due to animal parasites is practically a complete course in parasitology.

All in all, nothing except the highest praise can be given to the authors, who not only have compiled as fine a text book in dermatology as can be placed within two covers, but also have devised a particularly interesting and unusually attractive method for the citation of references, which form in themselves an almost indispensable adjunct to the library of any dermatologist. There are 1452 illustrations in black and white and 21 in full color. This book should be on the bookshelf of every dermatologist.

Aids to Dermatology and Venereal Disease Robert M. B. Mackenna. Second edition. 284 pp. Baltimore: The Williams & Wilkins Co., 1939. \$1.25.

This small handbook by a well known dermatologist is unusually complete, clearly readable and well organized. It considers many aspects of a large number of the commoner skin diseases in a succinct form. The format of the book lends itself to quick reference. Although this was published early in 1939, several important contributions which were well established by then were omitted, for example, the so-called "quick" tests for syphilis, such as the rapid Kline and rapid Hinton tests, Marpharsen as an important anasyphilitic drug, and the intradermal test for chancroid using a vaccine of the Ducrey bacillus, these omissions are, however, not very serious for a small book with its limited space.

The book is unusually free from the frequent mention of patent remedies which occurs so commonly in many English and Continental texts. It also lacks the strange sounding descriptive dermatology that is frequently found in books not published in America. Although it has the shortcoming of all small, concise books in its tendency to dogmatism, most of the controversial aspects are fairly well covered. One can, of course, take exception to numerous sentences here and there, such as "X-rays are of considerable therapeutic use in psoriasis." Generally, however, this is a very commendable book, not only for students but for general practitioners, particularly in view of its low price.

The Doctor Prescribes Music: The influence of music on health and personality Edward Podolsky. 134 pp. New York: Frederick A. Stokes Co., 1939. \$1.50.

In these times there is so much to be learned that the average medical man in his unsuccessful effort to keep up to date is swamped by reading material. He attempts to select and choose those subjects which will contribute to his skill. No matter what he reads he attempts to derive information, added thought or some idea which becomes part of his being. The reviewer had hoped for just this when reading Podolsky's book, but found that he doubted a good many of the statements in the text and questioned the interpretations of the effects of music on the physiology of the organism. Although the reviewer prefers to hear music than read about it, he could not see any scientific relation between emotional experiences and the reflexes. There is no tool to measure emotions or sensations or the therapeutic value of an emotional experience.

NUMBER 10

COMBINED DEGENERATION OF THE SPINAL CORD IN PERNICIOUS ANEMIA*

The Results of Seven Years' Experience with Parenteral Liver Therapy

MAURICE B. STRAUSS, M.D.,† PHILIP SOLOMON, M.D.,‡ and HERBERT J. FOX, M.D. §

BOSTON

IN MAY, 1935,¹ there was published the first comprehensive report from this clinic on the efficacy of parenteral liver therapy in the treatment of the neural manifestations of pernicious anemia. At that time it appeared evident that the spinal-cord lesions of otherwise uncomplicated pernicious anemia could be completely arrested by adequate parenterally administered liver extract. Furthermore, it was stated that patients with pernicious anemia without neural lesions would not develop spinal-cord degeneration if adequately treated. These conclusions were based on a study of 26 patients with marked spinal-cord lesions and 80 patients with minimal or no neural lesions, treated for an average period of three years. We have been able to continue observations on 21 of the first group and 64 of the second group for an additional four years, so that this report is based on 85 patients observed for an average period of seven years. This length of time warrants the drawing of conclusions which probably will not be altered in the future.

The general procedure outlined in the previous report has been continued. The patients received intramuscularly Solution Liver Extract Lilly (N.N.R.)^{||} prepared according to the method of Strauss, Taylor and Castle.² It is estimated that this material contains about one USP unit to the cubic centimeter. It is an aqueous solution of "Fraction G" of Cohn, Minot and their associates³ and contains many other substances present in liver besides the hematopoietically active material for pernicious anemia. Most of the patients received 10 cc of this extract at weekly intervals.

A few received as much as 10 cc. three times a week, and others as little as 10 cc every three weeks. The keynote of treatment remained, as before, the administration of more extract than was necessary merely for the maintenance of normal blood values.

RESULTS

The 21 patients with marked involvement of the cord had spasticity or ataxia, or both, resulting in definite disturbances in locomotion. With out exception these patients also had paresthesias in the hands and feet, and all had either diminished or absent vibratory sense in the legs and moderate to marked muscle weakness. Impotence, not due to age, or sphincter disturbances were encountered in five patients. Girdle sensations were common.

The average red-blood-cell count during the period of adequate treatment was 4,800,000, the hemoglobin 94.6 per cent (147 gm per 100 cc.) and the color index 0.98.

In no single case did any objective neurologic sign become more marked during the seven year period of treatment, nor did an abnormal sign not previously present, appear in any of the 21 patients with marked spinal-cord involvement. This indicates a complete arrest of the degenerative process. Improvement in strength, ability to get about and general subjective improvement of greater or less degree appeared in every patient during the first two or three years of treatment, as was noted in the previous publication. Objective signs due to peripheral nerve involvement disappeared in general within six months after beginning treatment. Objective signs of spinal cord disturbance occasionally disappeared or became less marked during the first year or two of adequate treatment, but thereafter remained unchanged.

‡Assistant in medicine, Harvard Medical School; assistant resident physician, Thorndike Memorial Laboratory, Boston City Hospital.

The 64 patients without marked neural lesions had either no signs referable to the nervous system or else evidence of mild lesions not interfering with their ability to walk. Not only is it statistically certain that many of these individuals would have developed crippling spinal-cord damage if inadequately treated over a period of seven years, but we have ourselves observed during this time a number of untreated or inadequately treated patients who have developed severe spinal-cord degeneration. In none of these 64 patients adequately treated for seven years has any further evidence of neural damage appeared. This indicates that adequate therapy prevents the development of combined degeneration of the spinal cord in patients with pernicious anemia.

DISCUSSION

Our earlier communication¹ listed some of the more important studies concerning the effect of therapy on the neural lesions of pernicious anemia. At that time it appeared that, although there was considerable difference of opinion, most workers who had employed large quantities of liver, liver extract or dried stomach reported favorable results. A survey of literature not included in the previous report shows that the preponderant opinion is optimistic. Mills,⁴ Farquharson,⁵ Murphy,⁶ Schilling,⁷ Allen,⁸ Schaller and Newman,⁹ Cohen,¹⁰ Greenfield and O'Flynn,¹¹ Haden¹² and many others have all reported satisfactory results in the treatment of combined degeneration of the spinal cord in pernicious anemia.

Furthermore, Suh and Merritt¹³ have noted that patients with combined degeneration of the spinal cord without other obvious evidence of pernicious anemia show no progression if treated with adequate amounts of liver extract by the parenteral route.

However, at least three reports which were not available until after our previous communication had gone to press have disagreed with the generally accepted belief that adequate liver therapy will arrest the progress of the neural lesions of pernicious anemia. Grinker and Kandel¹⁴ state "Quantities of liver in excess of that necessary to maintain a normal blood level are wasted. In our series of cases progression of symptoms and signs occurred in patients under continuous and adequate liver therapy with blood counts within normal limits." The highest recorded counts for these 10 cases were 41, 36, 40, 43, 50, 40, 44, 36, 31 and 38 $\times 10^6$ red blood cells, an average of 4,000,000 cells. Only one of these counts can be considered within normal limits, and thus liver therapy was obviously inadequate. No attention whatsoever was paid to the size of the cells, which

is more important than the actual level. The aim should be to restore the blood to normal in all respects so that the mean corpuscular volume and Price-Jones curves fall within approximately the normal range.

Needles¹⁵ in 1936 concluded "In some cases liver therapy prevents the onset of myelopathy, in others it does not." This statement was based on a study of 13 cases, in 6 of which therapy was admittedly inadequate, and in the remaining 7 no data are given by which the reader may judge of the adequacy of treatment. However, Needles does state "Of the patients who formed the basis for this study, it so happened that none who received sufficient treatment showed more than insignificant neurologic signs—and then in several cases not definitely attributable to subacute combined degeneration—while four showed no signs whatever."

Goldhamer, Bethell, Isaacs and Sturgis¹⁶ reported in 1934 that 34 per cent of 103 inadequately treated cases of pernicious anemia with neural lesion showed an unfavorable progression of neural signs in contrast to 8 per cent of 182 "adequately" treated patients. However, the criterion of "adequate" treatment was an erythrocyte count of 4,000,000 or higher—a fallacy which has been discussed above. The very fact that over four times as many patients showed progressive lesions with little treatment as did those with more treatment suggests that truly "adequate" treatment might have prevented any unfavorable progression of neural lesions. Furthermore, in a recent review Sturgis¹⁷ states "We have never observed objective signs of cord changes develop or progress during a period when the blood has been uniformly normal. Having this knowledge, the intensive treatment of the anemia is certainly the obvious and logical principle upon which our treatment should be based."

It is apparent from this analysis that the above authors who have reported failure to arrest the progress of the neural lesions of pernicious anemia have all failed to administer sufficient therapy to their patients. A word may well be said here as to just what is adequate treatment for the individual patient. First, material must be given to maintain the blood values at normal in every respect. Not only should the red cells number 4,500,000 or higher, but the mean corpuscular volume should be below 100 cu microns, and the color index 1.0 or below. Second, there must be no symptoms of any nature, such as glossitis or indigestion, attributable to pernicious anemia. Third, and most important, should there be any recurrence at any time of persistent numbness, tingling or other paresthesia of the extremities,

the dose of liver extract must be increased, usually doubled. Fourth, if the patient presents any other subjective manifestations that might be attributed to progression of the spinal-cord lesion, the dose should be doubled. The experience we have had establishes the fact that over an average period of seven years adequate therapy as described above has been effective in preventing further spinal-cord damage in patients who already have fairly marked lesions and has prevented the development or unfavorable progression of lesions in patients with no or minimal damage.

SUMMARY AND CONCLUSIONS

Twenty-one patients with pernicious anemia and advanced combined degeneration of the spinal cord were treated by the intramuscular injection of adequate amounts of liver extract for an average period of seven years. Complete arrest of the neural lesions occurred in every case.

Sixty-four other patients with pernicious anemia and little or no neurologic disturbances were treated in the same manner over an average period of seven years. In none of these patients was there any evidence that spinal-cord lesions progressed or developed under treatment.

The conclusion stated in 1935, now amplified by four additional years of experience, may be restated at this time. By means of appropriate

parenteral liver extract therapy for each case, the spinal-cord lesions of pernicious anemia may be prevented from developing or, having appeared, may be completely arrested.

REGIONAL ILEITIS*

SAMUEL F. MARSHALL, M.D.†

BOSTON

REGIONAL ileitis is one of the most interesting disease entities that has come to the attention of internists and surgeons during the past few years. Benign nonspecific granulomatous tumors of the bowel had been recognized and described for many years before attention was directed to regional ileitis as a clinical entity by Crohn, Ginzburg and Oppenheimer¹ in 1932. Certainly it is due to these writers that the clinical condition received proper recognition and that the course of the disease, together with the roentgenologic picture and the treatment, has been put on an established basis. Inflammatory tumors of the bowel were recognized and described in this country by Senn² as early as 1895. Later Braun³ (1909) published a report of the disease, and in

1923 Moschowitz and Wilensky⁴ described granulomatous tumors of the bowel in 4 patients.

Many reports fill the literature since the first description by Crohn and his associates, and much has been added to the detailed characteristics of the disease, both as to its recognition and as to the type of treatment, together with the fact that it responds so favorably to surgical treatment. Of special interest are reports of cases by other writers, notably Meyer and Rosi,⁵ Mock,⁶ Erdmann and Burt,⁷ Brown, Bagen and Weber,⁸ Homans and Hass,⁹ Mixter¹⁰ and Adams¹¹. Jackson¹² in 1937, in a collective review of American literature on this subject found 219 cases reported since Crohn's original article and added descriptions of 4 more. Crohn¹³ further reports 110 personally observed cases, in 73 of which the diagnosis was confirmed by operation.

The present study of regional ileitis is based on

Furthermore, Suh and Merritt¹³ have noted that patients with combined degeneration of the spinal cord without other obvious evidence of pernicious anemia show no progression if treated with adequate amounts of liver extract by the parenteral route.

However, at least three reports which were not available until after our previous communication had gone to press have disagreed with the generally accepted belief that adequate liver therapy will arrest the progress of the neural lesions of pernicious anemia. Grinker and Kandel¹⁴ state "Quantities of liver in excess of that necessary to maintain a normal blood level are wasted. In our series of cases progression of symptoms and signs occurred in patients under continuous and adequate liver therapy with blood counts within normal limits." The highest recorded counts for these 10 cases were 41, 36, 40, 43, 50, 40, 44, 36, 31 and 38×10^6 red blood cells, an average of 4,000,000 cells. Only one of these counts can be considered within normal limits, and thus liver therapy was obviously inadequate. No attention whatsoever was paid to the size of the cells, which

is more important than the actual level. The aim should be to restore the blood to normal in all respects so that the mean corpuscular volume and Price-Jones curves fall within approximately the normal range.

Needles¹⁵ in 1936 concluded "In some cases liver therapy prevents the onset of myelopathy, in others it does not." This statement was based on a study of 13 cases, in 6 of which therapy was admittedly inadequate, and in the remaining 7 no data are given by which the reader may judge of the adequacy of treatment. However, Needles does state "Of the patients who formed the basis for this study, it so happened that none who received sufficient treatment showed more than insignificant neurologic signs—and then in several cases not definitely attributable to subacute combined degeneration—while four showed no signs whatever."

Goldhamer, Bethell, Isaacs and Sturgis¹⁶ reported in 1934 that 34 per cent of 103 inadequately treated cases of pernicious anemia with neural lesion showed an unfavorable progression of neural signs in contrast to 8 per cent of 182 "adequately" treated patients. However, the criterion of "adequate" treatment was an erythrocyte count of 4,000,000 or higher—a fallacy which has been discussed above. The very fact that over four times as many patients showed progressive lesions with little treatment as did those with more treatment suggests that truly "adequate" treatment might have prevented any unfavorable progression of neural lesions. Furthermore, in a recent review Sturgis¹⁷ states "We have never observed objective signs of cord changes develop or progress during a period when the blood has been uniformly normal. Having this knowledge, the intensive treatment of the anemia is certainly the obvious and logical principle upon which our treatment should be based."

It is apparent from this analysis that the above authors who have reported failure to arrest the progress of the neural lesions of pernicious anemia have all failed to administer sufficient therapy to their patients. A word may well be said here as to just what is adequate treatment for the individual patient. First, material must be given to maintain the blood values at normal in every respect. Not only should the red cells number 4,500,000 or higher, but the mean corpuscular volume should be below 100 cu microns, and the color index 1.0 or below. Second, there must be no symptoms of any nature, such as glossitis or indigestion, attributable to pernicious anemia. Third, and most important, should there be any recurrence at any time of persistent numbness, tingling or other paresthesia of the extremities,

icians and surgeons and has been thought to be tuberculosis of the terminal ileum and cecum resection being done on this basis. In our 29 operated cases, 4 patients were referred to the clinic following previous laparotomy, at which time the surgeon

phatic disease of the mesentery, with the production of marked lymphedema of the bowel wall, and it has been suggested that there may be some association between regional ileitis and lymphadenitis of early childhood, so commonly seen,

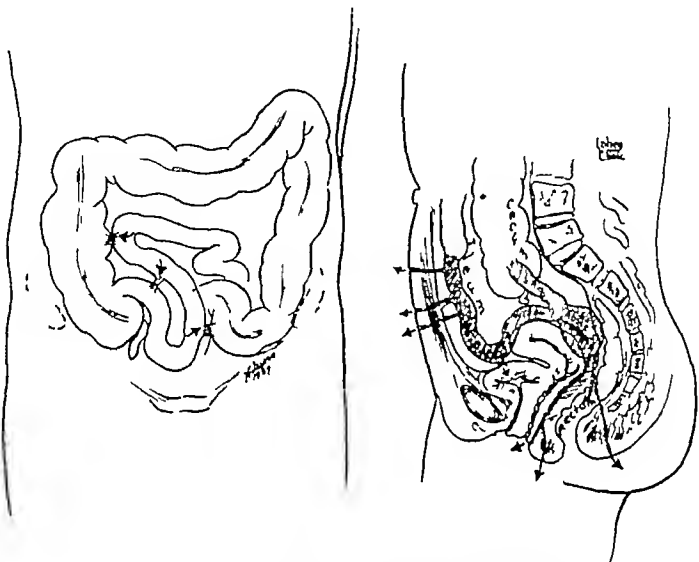

FIGURE 2. Types of Fistulas Encountered at Operation.

The diagram on the left shows the fistulous tracts formed between the ileum and an adjacent loop of small bowel, the terminal ileum, the ascending colon and the sigmoid. That on the right illustrates fistulous tracts noted extending through the abdominal wall (the commonest type) and into the bladder and types of perirectal fistulas.

had diagnosed the condition as tuberculosis of the small bowel. Two patients were confined to tuberculosis sanatoriums for some time before being referred for abdominal surgery. Crohn states that the disease is definitely not caused by the tubercle bacillus, and in none of his specimens has this bacillus been demonstrated or recovered. The disease is chronic, it progresses insidiously with the development of a palpable abdominal mass, and is complicated by the production of internal and external fistulas and later, by obstruction due to the marked contraction and narrowing of the lumen of the bowel.

The cause of the disease has not been established, although there are many theories as to its origin. The work by Felsen¹¹ appears to suggest a dysentery bacillus as the causative agent, but even in cases reported by him such bacilli have not been isolated from the resected specimens. Another theory has been that the condition is due to lym-

phatic disease of the mesentery, with the production of marked lymphedema of the bowel wall, and it has been suggested that there may be some association between regional ileitis and lymphadenitis of early childhood, so commonly seen,

which may possibly be associated with small lesions of the mucosa which are unrecognized. It has been emphasized in the literature that the disease has an especial predilection for the Hebrew race, but in our series of 29 operated cases there were only 3 Jewish patients. With the accumulation of further reports in this country and abroad, it appears that the disease may occur in any race and in any class of people. The sex distribution also is of interest, most of the reports showing the disease to occur more commonly in men than in women, the proportion being 2:1 or 3:2. In our series of operated cases there were 13 men and 16 women, which is somewhat a reversal of other reported series.

Regional ileitis is apparently a disease of young adults, and most commonly occurs in the third and fourth decades (Table 1). Twenty of our cases confirmed by operation occurred in individuals be-

tween twenty and forty years of age The youngest patient was sixteen, and the oldest sixty-nine

Regional ileitis is characterized by pain in the right lower quadrant, associated with nausea, diarrhea, loss of weight and anemia In the later stages a palpable mass frequently is readily made out The course of the disease is that of a chronic, progressive inflammatory process which may persist for months or even years However, the onset

TABLE 1 Age Distribution in 29 Operated Cases

| AGE | NO OF CASES |
|-------|-------------|
| 10-20 | 4 |
| 20-30 | 11 |
| 30-40 | 9 |
| 40-50 | 2 |
| 50-60 | 2 |
| 60-70 | 1 |

may be acute and characterized by symptoms easily confused with those of acute appendicitis The patient complains of pain, associated with nausea and occasionally vomiting, and localized in the right lower quadrant of the abdomen, and to all intents and purposes the condition closely simulates a genuine attack of appendicitis However, the common course is that of a long-standing chronic disease, and a careful evaluation of the history and symptoms frequently suggests the true nature of the process within the abdomen

Typical cases of regional ileitis have been described in detail so frequently that the lesion is in the majority of cases correctly diagnosed Certainly the lesion in the terminal ileum is quite characteristic, and should the findings noted in the appendix not be consistent with the preoperative diagnosis of appendicitis, the ileum should certainly be carefully examined By so doing many errors can be avoided This confusion with acute appendicitis is not unusual, and of our 29 patients operated on, 15 had had a previous appendectomy, the true nature of the disease apparently being recognized in only 2 cases Seventeen patients had had operations previous to admission to the clinic. Seven had had two or more abdominal operations, and 1 patient had had seven previous abdominal operations without the true pathological condition's being recognized As stated before, the condition is frequently confused with tuberculosis

Symptoms of intestinal obstruction are not uncommon, though a complete obstruction rarely occurs The patients complain of distention associated with crampy abdominal pain and vomiting, and roentgenological examination frequently shows marked diminution in the lumen of the bowel, with dilated loops proximal to the area of stenosis

One of the commonest complications is the occurrence of fistulas (Fig 2), which may be either

internal or external in their course With the progression of the inflammatory process in the bowel and with ulceration of the mucosa, perforations frequently occur, and these may penetrate

FIGURE 3 "String Sign" in the Terminal Ileum
It is indicated by the arrow and is a typical x-ray finding in cases of regional ileitis Note the dilated and obstructed loop of small bowel proximal to the narrowed terminal ileum

into the adjacent adherent loops of bowel, commonly into the sigmoid or cecum or into other loops of the small bowel In a young woman with an acute fulminating enteritis involving the terminal ileum, acute perforation occurred, death resulting from generalized peritonitis Perforation may also occur with the formation of an abscess, 3 of our patients were admitted with an abscess in the right lower quadrant of the abdomen, which was taken to be an appendiceal abscess until the true nature of the process was recognized at operation Perforation took place into the sigmoid in 1 case and into the urinary bladder in 1 Perforation into the adjacent ascending colon is not uncommon, and this occurred in 2 cases

External fistulas on the anterior abdominal wall are common (Fig 2), and usually follow one or more previous abdominal operations in which an appendectomy has been done under the impression that the symptoms were due to appendicitis The initial complaint in 7 cases in which resection for regional ileitis was successfully done was

that of a draining fistula in the right lower quadrant. All these fistulas followed appendectomy with drainage. One patient gave a history of having had frequent fistulas for more than two years

FIGURE 4 X Ray Findings in Regional Ileitis.

The patient was a man aged twenty-six with symptoms for over six years. The small bowel is obstructed by a cicatrizing process. Note the marked narrowing ("string sign") of the terminal ileum. The arrow points to a fistulous tract between adherent involved loops of ileum. Operation a two-stage resection of the ileum and ascending colon was followed by recovery.

before the nature of the condition was recognized. Such patients present themselves to the surgeon with a history of previous right lower quadrant pain followed by appendectomy, with no improvement in their distress and with the development of a fecal fistula in the right lower quadrant. In most cases fistulous tracts will be demonstrated to arise from a terminal ileum affected with a cicatrizing, granulomatous, inflammatory process. Such a history given by a patient should make the examiner suspect regional ileitis, and the diagnosis can be readily established by serial roentgenograms of the intestine and by roentgenological examination following Lipiodol injection of the fistulous tract.

The final diagnosis is established by roentgenological examination (Figs 3 and 4). A barium meal is administered by mouth and roentgenological examination is made after the third, fourth, fifth sixth and tenth hours. Characteristic filling defects are noted in the terminal ileum, and in the advanced cases marked stenosis of the

bowel reduces the lumen so that only a thin, irregular linear shadow is seen, presenting the "string sign" that has been described by Kantor¹⁵. The passage of barium through the ileum is delayed, and dilatation of the ileum proximal to the filling defects is readily made out. Areas of constriction alternating with segments of normal or slightly dilated bowel may be demonstrated. The filling defects of the terminal ileum just proximal to the cecum are characteristic, and the roentgenological findings taken in conjunction with the history establish the diagnosis quite accurately in the large majority of cases. Examination after administration of a barium enema should also be made, in order to rule out other lesions of the colon and to demonstrate the possible involvement of the cecum and colon with the granulomatous, inflammatory process.

FIGURE 5 Extensive Involvement of the Intestine with Cicatrizing Enteritis

There is residual barium in the stomach also areas of thickening and narrowing of the small bowel alternating with dilated obstructed loops. The lesion apparently starts in the proximal jejunum and extends through the terminal ileum. The process was too extensive for surgical removal.

There has been much discussion as to whether the surgical management should consist of radical removal of the involved bowel or the more conservative procedure of ileocolostomy. It is likely that spontaneous remission of the disease occurs

in many cases, but certainly in the advanced cases with marked granulomatous changes in the bowel and with stenosis and obstruction and ulceration, the only possibility of a permanent cure lies in removing the affected segment of bowel. In view of the tendency for these ulcerated areas to per-

hill and there is little to offer in surgical management (Fig 5). It is also generally conceded that operation in the acute phases of regional ileitis should be avoided. If it becomes necessary to perform a laparotomy in order to establish the diagnosis and rule out acute appendicitis, conservatism

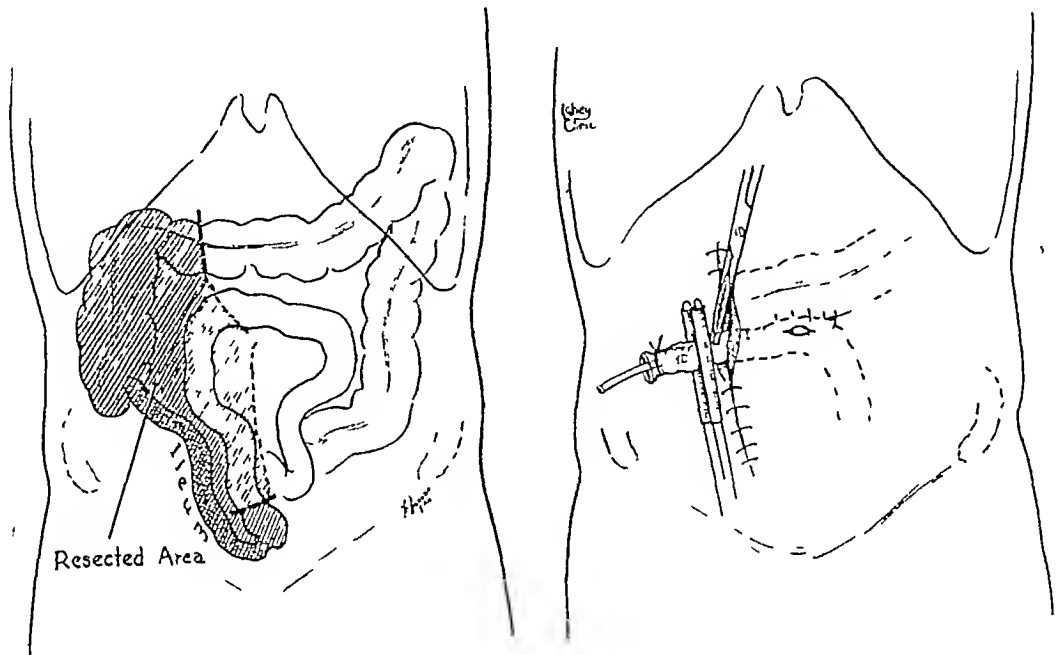

FIGURE 6 Two-Stage Resection for Regional Ileitis

In the diagram on the left the shaded area shows the section of bowel and the mesenteric attachment that are removed when the terminal ileum is involved with enteritis. That on the right shows how a Mikulicz spigot is formed between the ileum and the transverse colon, following removal of the affected bowel. The loop of ileum is staggered to permit immediate drainage of the bowel through a catheter.

forate, and the frequency of fistula formation either between adjacent loops of intestine or externally, resection should be considered early and is desirable for most cases, if the general condition of the patient permits such a radical operation. Certainly the large majority of patients with this

should be practiced, and the abdomen closed without intra-abdominal surgery or after a simple ileocolostomy has been established. Certainly in the presence of definite acute regional ileitis, appendectomy should not be done, as there is considerable risk of establishing an external fistula. Among 15 of our patients who had previously had an appendectomy, there were 8 with external fistulas. The 2 deaths in our operated cases occurred in patients in the acute phase of the disease, one in the presence of an acute regional ileitis associated with an abscess, and the other in an acute fulminating process in which an ileocolostomy was done.

TABLE 2 Type of Operation and Number of Deaths in 29 Cases of Regional Ileitis

| TYPE OF OPERATION | NO OF CASES | NO OF DEATHS |
|---|-------------|--------------|
| Resection with primary anastomosis | 5 | 0 |
| Preliminary colostomy and later resection | 4 | 0 |
| Mikulicz resection | 13 | 0 |
| Ileocolostomy only | 4 | 1 |
| Drainage of abscess | 3 | 1 |

disease ultimately require surgical treatment for permanent relief of their symptoms, and so far, the best results have been obtained by operation. It is conceded that the occasional patient with widespread involvement of the small intestine may of necessity be given medical treatment, because it is impossible to remove all the diseased bowel, but the course of these cases is progressively down-

Resection of the affected loops of intestine was carried out in 22 cases without a fatality (Table 2). In 17 of these patients resection was performed in two stages.

We prefer to carry out resection of the terminal ileum, cecum and ascending colon by the plan devised by Mikulicz for the left colon (Fig 6). Lahey¹⁰ has utilized this type of resection for all lesions of the right colon, and has described in detail the method, which can be carried out with

a much greater margin of safety than that accompanying a resection in one stage. Because in a small percentage of cases the cecum and ascending colon may be involved in the disease process, and also because the ileocecal junction is ulcerated in over half the cases, the cecum and ascending

FIGURE 7 Roentgenogram after a Barium Enema
This shows the ileocolostomy opening after resection of the ileum and ascending colon for regional ileitis

colon are removed with the terminal ileum. It must be re-emphasized that the margin of safety in performing two-stage resections of the terminal ileum and ascending colon is much greater than that in attempting to do such an extensive procedure at one sitting. These patients are usually seriously ill, in a poor state of nutrition, have had their condition for a long period of time and present extremely poor operative risks. The extent of the operation may be considerable when freeing adhesions, and frequently abscesses, as well as fistulous communications between adherent loops of the bowel, are broken into. To attempt such an extensive resection with immediate primary anastomosis greatly increases the operative hazard, and is unjustifiable in view of the excellent results and the comparative safety with which a two-stage Mikulicz type of resection can be carried out in a large majority of cases. The affected loop of the terminal ileum is resected, together with the cecum and ascending colon, and a Mikulicz spur is formed between the terminal ileum and the resected end

of the transverse colon, which has been brought out through an abdominal incision. The ileal loop is staggered in order to permit immediate drainage of the intestine with a catheter, which is tied in at the end of the ileum. At the end of a week the spur between the resected ends of the ileum and colon is gradually cut down, and it is completely divided by the time the patient is discharged from the hospital, which is usually sixteen or seventeen days after operation. These patients are then readmitted six weeks later for closure of the enterostomy opening, which is composed of the ends of the transverse colon and the ileum (Fig. 7).

The postoperative course of these patients who have had a two-stage resection after the Mikulicz plan is uneventful and extremely satisfactory. They usually show great improvement in general health in the six weeks following resection before closure of the enterostomy opening. Considerable gain in weight may be expected, and one patient in our series gained 40 pounds in this interval.

The best results obtained in the surgical management of patients with regional ileitis have been those following resection of the involved loops of bowel. Certainly palliative operation does not accomplish this, and secondary operation may prove to be necessary later, as occurred in one of our patients who had had a previous ileocolostomy, the disease process continuing in an involved loop of bowel until a successful resection was carried out. The course of all our patients who have had removal of the involved segments of bowel has been followed at intervals regularly since operation, and in the majority of cases there has been complete restoration of health.

Recurrence of the disease has been noted in 2 patients. One was a young man whose case possibly should not be classified as a recurrence because the extent of the involvement precluded removal of all the involved bowel. A considerable portion of the ileum (150 cm.) was removed at operation, but other mildly affected loops of bowel were also noted at operation and could not be resected because of the extent of the lesion. The lesions that were left intact were minimal and were characterized by some thickness of the bowel wall by hyperemia and by small lymph nodes in the mesentery. The chief symptom has been mild abdominal discomfort, which has been controlled very satisfactorily by diet. The patient has gained in weight, has apparently remained in good health under medical management and has maintained a satisfactory weight level. Recurrence following resection took place in a young Jewish woman whose symptoms were chiefly those of mild abdominal discomfort accompanied occasionally by

three or four bowel movements a day. With the exception of the continued discomfort and diarrhea, her general health has been excellent. Her course was followed over a period of four years following resection. She was finally submitted to secondary operation because roentgenographical examination showed fresh involvement of the terminal ileum. At operation resection again was necessary, with removal of the terminal 60 cm of the ileum, establishing an ileocolostomy with the transverse colon.

We believe that the operative risk is considerably reduced by using the two-stage method of resection. No death has resulted following radical resection in our hands.

SUMMARY

Forty-eight cases of regional ileitis observed over a period of seven years are reported.

Twenty-nine patients were operated on, with 2 deaths following operation.

Resection of the involved loops of intestine was performed in 22 patients without a fatality.

It is our opinion that the two-stage method of resection is the operation of choice. Extensive resections employing the Mikulicz plan were used in 17 cases, with uneventful convalescence in every case.

Recurrences are probably associated with incomplete removal of the affected bowel, and for this reason we advocate wide excision of the affected loop. We believe that the cecum should be removed in all cases in which the terminal ileum is involved.

MASSACHUSETTS MEDICAL SOCIETY

PROCEEDINGS OF THE COUNCIL

Stated Meeting, February 7, 1940

A STATED meeting of the Council of the Massachusetts Medical Society was held in John Ware Hall, Boston Medical Library, 8 Fen way, Boston, on Wednesday, February 7, at 10.30 a.m. The President, Dr. Walter G. Phippen, Essex South, was in the chair, and 222 councilors were present (Appendix No. 1).

The Secretary presented the record of the meeting of the Council of October 4, 1939, as published in the *New England Journal of Medicine* issue of November 2, 1939. The President declared the record approved as published.

Obituaries of six councilors, who had died since the last meeting were read by the President as follows:

DR. J. FORREST BURNHAM of Lawrence died January 26 in his seventy-second year.

After attending Harvard University Dr. Burnham received his degree from the Harvard Medical School in 1901.

He was a member of the Council of the Massachusetts Medical Society from the Essex North District from 1920 to 1939. From 1914 to 1920 he was an alternate delegate and from 1920 to 1936 a delegate to the House of Delegates of the American Medical Association. He had served as secretary of the Essex North District Medical Society.

Dr. Burnham was secretary of the staff of the Lawrence General Hospital for many years and was a member of the Lawrence Medical Club and a fellow of the American Medical Association.

His widow survives him.

DR. WALTER A. LANE of Milton died January 21 in his sixty-eighth year.

He attended Dartmouth College and received his degree, cum laude, from the Harvard Medical School in 1899.

Dr. Lane was a fellow of the American Medical Association and a member of the New England Pediatric Society. He served as vice-president of the Massachusetts Medical Society in 1932 and 1933 as a member of the Committee on Public Relations from 1932 to 1937 and as a delegate to the House of Delegates of the American Medical Association in 1937. He had also served as president of the Norfolk District Medical Society.

He was a director and consultant of the Sharon Sanatorium and from 1906 to 1924 he had served as Milton school physician.

His widow, a son and a daughter survive him.

DR. CHARLES MOLINE, of Sunderland died November 15 in his sixty-fourth year.

Born in Motala, Sweden, he went to Sunderland when he was twelve years old. He attended Harvard University and received his degree from the Harvard Medical School in 1903.

He was a fellow of the American Medical Association

and was secretary of the Franklin District Medical Society for twenty years.

His widow and two daughters survive him.

DR. HARRY R. NYE, of Leominster died January 8 in his sixty-ninth year.

He received his degree from the University of Vermont College of Medicine in 1900. He was a member of the staff of the Leominster Hospital for twenty-seven years.

He was a fellow of the American Medical Association, had served as a member of the Committee on Public Relations of the Massachusetts Medical Society for several years and had been president of the Worcester North District Medical Society.

His widow and one son, Dr. Lucius S. Nye, survive him.

DR. DAVID D. PRATT of New Bedford, died January 29 in his fifty-ninth year.

He attended Dartmouth College and received his degree from the Harvard Medical School in 1906.

He had been a practicing physician in New Bedford since 1907. He was a fellow of the American Medical Association and a member of the New Bedford Medical Society.

His son and daughter survive him.

DR. THOMAS J. SCANLAN of West Roxbury died October 18 in his sixty-eighth year.

He attended Tufts College Medical School receiving his degree in 1903. At the time of his death Dr. Scanlan was chairman of the Board of Trustees of the Boston State Hospital. He had served as a member of the staff of the Boston Dispensary consulting surgeon at Deer Island Hospital, medical examiner for the City of Boston Law Department, member of the gynecological staff of St. Elizabeth's Hospital, chief consultant at the Foxboro State Hospital and surgeon at the Winthrop Community Hospital.

Dr. Scanlan was a fellow of the American Medical Association and of the New England Obstetrical and Gynecological Society.

His widow, a sister and two brothers survive him.

The Council stood in silent tribute to the memory of these men.

The report of the Auditing Committee (Appendix No. 2), signed by Dr. Ezra E. Cleaves, chairman, and Dr. Edwin B. Dunphy, was read by the treasurer, Dr. Charles S. Butler. It was voted to accept the report as presented.

The report of the Treasurer (Appendix No. 3) was presented by him and was duly accepted. On the motion of Dr. Charles E. Mongan, Middlesex South, the Council expressed its appreciation of the services of Dr. Butler in conserving the funds of the Society.

On motion of Dr. Butler, the Council voted

permission to reduce the book value of one security purchased twelve years ago, and for years in default, namely bonds of the Conveyancers Title Insurance and Mortgage Company

REPORTS OF STANDING COMMITTEES

Financial Planning and Budget

The report (Appendix No 4) was presented by the chairman, Dr John Homans, Suffolk. This report took the form of the budget recommended for the current year and mimeographed copies had been placed in the hands of every councilor. On motion of Dr Edward Mellus, Middlesex South, and after some discussion, it was voted to amend the budget by increasing the item of "returns to district societies" from \$4000 to \$5000. Following this the budget was approved as amended.

Membership

The chairman, Dr H Quimby Gallupe, Middlesex South, presented the report of the committee (Appendix No 5). During the discussion, two names were taken from the list of those to be deprived of membership. The report was then adopted recommending that eight fellows be allowed to retire, thirty-five be allowed to have their dues remitted, eight be allowed to resign, fourteen be allowed to change their districts without change of legal residence, and three be recommended for affiliate fellowship in the American Medical Association.

Arrangements

The report of the committee (Appendix No 6) was presented by the chairman, Dr Augustus Thorndike, Jr, Suffolk, and was duly adopted.

The dates set are May 21 and 22, in Boston.

State and National Legislation

The chairman, Dr Charles C Lund, Suffolk, made a verbal report. He stated that, since there is no state legislature in 1940, the committee has not been so busy as usual. One meeting had been held to take up a few items. A copy of the bill, presented to the United States Senate by Senator Wagner, of New York, is under study by the committee. This bill proposes to authorize the expenditure of \$10,000,000 in support of President Roosevelt's plan to establish small rural hospitals in areas where the need can be shown and where arrangements can be made for the support of such an institution. The report was accepted.

Public Health

The report (Appendix No 7) was presented by the chairman, Dr Francis P Denny, Norfolk, and was duly accepted.

The resolution previously submitted by Dr Henry M Landesman, Norfolk, was recommended for adoption by the committee and was approved by the Council (Vote 85 in favor, 42 opposed).

REPORTS OF SPECIAL COMMITTEES

Cancer

The chairman, Dr Shields Warren, Suffolk, presented the report (Appendix No 8), which was accepted by the Council.

Postgraduate Instruction

The report (Appendix No 9) was presented by the chairman, Dr Frank R Ober, Suffolk, and was accepted. The Council then voted to adopt the recommendations of the committee as to the continuation of its work.

Committee Appointed to Support an Appropriation by Congress for the Construction of a New Building to House the Army Medical Library and Museum

In the absence of the chairman, Dr Henry R Viets, Suffolk, the report (Appendix No 10) was read by the Secretary and was accepted by the Council.

Committee to Study the Practice of Medicine by Unregistered Persons

The report (Appendix No 11) was presented by the chairman, Dr Richard Dutton, Middlesex East. It was voted to accept the report.

Dr Edward A Adams, Worcester North, moved that a copy of the report be sent to the Governor.

During the discussion which followed, Dr Charles C Lund, Suffolk, complimented the committee on its work but called attention to certain other phases of the problem. He stated that chiropractors, trichologists and others are advertising and practicing medicine. In his opinion the Board can do nothing to correct this evil without a large increase in its appropriation and a reorganization of the Board itself. He stated that the Public-Health Committee of the legislature recognized the need for more money for the Board but believed that the physicians must raise this money themselves. He expressed the hope that the committee would continue active and would go into other aspects of the situation. He pointed out that the report of the expenditures of the Board does not include all money spent by the Commonwealth since there are people who work for the Board and who are paid from other funds.

It was finally voted to adopt the report of the committee and to send a copy to the Governor. The chair announced that the committee would be continued.

Public Relations

The report (Appendix No 12) was read by the secretary of the committee, Dr Elmer S Bagnall, Essex North

Following the reading of the report, the Council went into executive session and discussed the report in detail. After the executive session was declared dissolved by the President, the Council voted to accept the report of the committee.

Discussion was resumed. In the opinion of some councilors the acceptance of the report and the adoption of the recommendations would at the same time indicate the approval of the Society of the conclusions on which the recommendations were based. The President ruled that this was the case.

Dr J Harper Blaisdell, Middlesex East, assumed that if the vote was passed the Council would there by express disapproval of the present plan of Health Service, Inc. but stated that the committee of five would have to consider it or any other plan which was brought to its attention.

Dr Nathaniel W Faxon, Suffolk, stated that a plan should not be condemned until it had been tried. He pointed out that many other plans had been prejudged and found lacking, whereas when put into operation they were successful.

The President pointed out that the Committee on Public Relations had decided to recommend the appointment of the committee so as to prevent prejudgment on any plan.

Dr Michael A Tighe, Middlesex North, pointed out that the recommendations of the committee were based on certain conclusions. He stated that no committee could assume the responsibility of policy-making for the Society, since this is a duty of the Council. He called attention to certain misinformation which had been rather widely circulated with reference to the American Medical Association. He stated that the Judicial Council of the American Medical Association had ordered the California State Medical Association to restore membership to certain individuals because the proper procedure had not been followed in the action taken to expel these individuals. The real issue concerning ethical practice had not been tried by the American Medical Association.

Various motions were proposed and amendments suggested. The Council finally called for the question on the original motion and voted to adopt the recommendation contained in the committee's report.

The Council recessed for the Cotting Luncheon from 1.30 to 2.30 p.m.

Restoration to Fellowship

Two restorations to fellowship (Appendix No 13) were authorized by the Council.

New committees to consider restoration for five fellows (Appendix No 14) were appointed by the President and confirmed by the Council.

APPOINTMENT OF DELEGATES

The President next introduced the matter of appointing delegates to the House of Delegates of the American Medical Association for two years beginning June 1, 1940.

On motion of Dr Edmond F Cody, Bristol South, Dr Phippen was placed in nomination as one of the delegates from Massachusetts. The President announced the nomination of delegates and alternates as follows:

| <i>Delegates</i> | <i>Alternates</i> |
|--------------------------------------|--------------------------------------|
| David D Scannell, Norfolk | Elmer S Bagnall Essex North |
| Dwight O Hara Middlesex South | Arthur W Marsh Worcester |
| Charles E. Mongan Middlesex South | Michael A. Tighe, Middlesex North |
| Walter G Phippen Essex South | John L. B. Vail Barnstable |

It was voted to close the nominations and to declare those named above as duly elected (See last paragraph under "Incidental Business").

The chair then nominated the following fellows as delegates to the meetings of the other New England state societies:

| | |
|----------------------|------------------------------------|
| <i>Maine</i> | Harold G Giddings, Middlesex South |
| | Olin S Petungill, Essex South |
| <i>New Hampshire</i> | Charles S. Benson, Essex North |
| | Edward A. Adams, Worcester North |
| <i>Vermont</i> | Peer P Johnson, Essex South |
| | John G Adams, Essex South |
| <i>Rhode Island</i> | J Frank Donaldson, Essex South |
| | Henry F Dauphin, Bristol North |
| <i>Connecticut</i> | Clarence E. Burr, Bristol South |
| | George L. Schadt, Hampden |

The Council voted to confirm the nominations and to elect the nominees.

On motion of the President, Dr Alexander S Begg, Norfolk, was selected as delegate to the Annual Congress on Medical Education and Licensure of the American Medical Association, to be held at the Palmer House, Chicago, February 12 and 13.

CONFIRMATION OF APPOINTMENTS

Confirmation of ad interim appointments was authorized by the Council as follows:

| |
|---|
| Dr Frank H. Lahay — Chairman, Committee on Publications |
| Dr William B. Breed — Member, Committee on Publications |

- Drs Halstead G Murray and Thomas L Shipman — Members, Committee on Industrial Health
 Dr Henry C Marble — Member, Committee to Consider Expert Testimony
 Dr Henry E Gallup — Member, Committee on Convalescent Care
 Dr Richard P Stetson — Voting member, Associated Hospital Service Corporation of Massachusetts
 Dr Roger I Lee — Councilor, Suffolk District
 Dr Robert W Buck — Councilor, Middlesex South District
 Drs Henry M Emmons and Norman A Welch — Councilors, Norfolk District
 Dr Frank M Howes — Councilor and Supervising Censor, Bristol South District
 Dr Carl C Persons — Censor, Bristol South District

INCIDENTAL BUSINESS

Dr Elliott P Joslin, Suffolk, called the Council's attention to a previous vote (October 7, 1936) empowering the President to appoint a committee of fellows who would have power to act on behalf of the Society in an advisory capacity to any medical school or college and to help direct such institution's efforts to develop and improve its facilities for teaching. In connection with this vote he reported on certain negotiations with Middlesex University School of Medicine. He referred to his address to the Society at the Worcester meeting and stated that subsequently he had received a request from the Middlesex University School of Medicine to become a member of the board of trustees and that he had declined the appointment. He likewise referred to his letter which was published in the *New England Journal of Medicine*, setting forth certain conditions which he thought ought to be fulfilled by the institution in question. He stated that the alumni of the school had publicly accepted the responsibility and that the president of the university had subsequently accepted the conditions. He informed the Council that this institution had fulfilled certain of the conditions laid down and that it is now in the process of endeavoring to secure the teaching beds required. He proposed that the President appoint a committee to consider the present situation at Middlesex and report at the next meeting of the Council with the possible submission of certain names for consideration for nomination to trusteeship of the Middlesex University School of Medicine.

Dr Joslin's motion was duly seconded. It was pointed out by Dr Butler that the Massachusetts Medical Society had no part in the selection of trustees to the boards of any of the other medical schools in the state and he questioned the advisability of establishing this precedent.

Dr Brainard F Conley, Middlesex South, questioned the advisability of taking action when the

institution had not as yet been acted on by the approving authority authorized by the state legislature.

Dr Lund pointed out that the American Medical Association has machinery for evaluating medical schools and that he did not believe it wise for the Society to adopt this type of co-operation at the present time.

Dr Charles E Mongan, Middlesex South, pointed out that many of the councilors had not returned to the meeting after luncheon and that he would be reluctant to see a vote without a thorough discussion before a larger number. He therefore moved that the recommendation be placed on the table for the next regular meeting of the Council. This motion was duly passed by the members present.

Dr Elmer S Bagnall, Essex North, called attention to the difficulties which occur in many localities in the administration of medical care for welfare recipients, old age recipients and veterans. He referred to the recent instance in Lawrence where it appears that irregularities and injustices had occurred. He therefore offered a resolution (Appendix No 15). After considerable discussion the chair ruled that the resolution should be referred to the Committee on Public Relations for further study.

Dr Edmond F Cody, Bristol South, introduced a resolution (Appendix No 16) which was adopted at the annual meeting of the Bristol South District last May. After some discussion it was moved to lay the matter on the table. This was confirmed by vote.

Dr Arthur W Marsh, Worcester, asked that his name be withdrawn as an alternate delegate to the House of Delegates of the American Medical Association because of physical disability. The President announced that he would abide by Dr Marsh's request and that he would appoint an alternate at a later date. (Dr Ernest L Hunt, Worcester, was appointed by the President following the meeting.)

The meeting adjourned at 3 15 p m

APPENDIX NO. 2

REPORT OF THE AUDITING COMMITTEE

The report of the examination of the books and accounts of the Massachusetts Medical Society for the twelve months ended December 31, 1939 made by Messrs. Hartshorn and Walter of Boston has been submitted to the attention of the Auditing Committee.

As the Auditing Committee, we have carefully examined the report of these certified public accountants, and approve the figures submitted by them.

EZRA E. CLEVELAND, Chairman
EDWIN B. DUNPHY

The Massachusetts Medical Society

8 Fenway

Boston, Massachusetts

Gentlemen

At the request of your treasurer, Dr Charles S Butler, we have examined the books and accounts of the Massachusetts Medical Society for the twelve months ended December 31, 1939, and submit herewith

SCHEDULE A Statement showing the balance sheet of the Massachusetts Medical Society, December 31, 1939

SCHEDULE B Statement showing the revenue and expenses of the Massachusetts Medical Society for the twelve months ended December 31, 1939

The cash on deposit in the banks has been reconciled with the bank statements. The cash receipts as recorded have been properly accounted for and disbursements are supported by vouchers or cancelled checks which were examined by us.

The securities and savings bank books in the various funds were examined by us or accounted for.

The accompanying balance sheet and related statement of revenue and expenses fairly present its position on December 31, 1939, and results of its operations for the year.

Respectfully submitted,

HARTSHORN AND WALTER
